Uniwersytet im. Adama Mickiewicza w Poznaniu

mgr inż. Anna Kawka

**Synteza, analiza spektroskopowa
oraz badania biologiczne *in silico* nowych
koniugatów steroidowych zawierających
układy triazolowe**

**Synthesis, spectroscopic analysis and *in silico*
biological studies of new steroid conjugates
containing triazole systems**

Rozprawa doktorska w formie cyklu artykułów naukowych

Poznań, 2025 r.

Praca doktorska została wykonana w Zakładzie Produktów Bioaktywnych
Wydziału Chemii
Uniwersytetu im. Adama Mickiewicza w Poznaniu

Promotor: prof. UAM dr hab. Tomasz Pospieszny

Promotor pomocnicza: dr inż. Hanna Koenig

*Pragnę wyrazić głęboką wdzięczność
Profesorowi UAM dr. hab. Tomaszowi Pospiesznemu,
mojemu Promotorowi, za nieocenione wsparcie, mądrość
i inspirację, które były filarami mojego rozwoju
naukowego. Pańska opieka i życzliwość uczyniły
tę współpracę czymś znacznie więcej niż tylko naukowym
doświadczeniem.*

*Moją serdeczne podziękowania kieruję do
Pani dr inż. Hanny Koenig,
której cierpliwość, wyrozumiałość
i nieoceniona pomoc towarzyszyły
mi w trakcie całego procesu tworzenia tej pracy.*

Michalinie,

*dziękuję za Twoje wsparcie, cierpliwość
i motywację, które sprawiły, że nigdy
nie przestałem wierzyć w siebie i swoje
możliwości.*

*Mojej Rodzinie,
za umożliwienie realizacji własnych celów, które
pozwoły mi dotrzeć do tego miejsca.*

*Pamięci mojego ukochanego Dziadka, którego
obecność na zawsze pozostanie
w moim sercu i którego miłość inspirowała mnie
na każdym kroku tej drogi.*

Życiorys naukowy

Urodziłam się 1 sierpnia 1997 roku w Inowrocławiu. W 2016 roku ukończyłam III Liceum Ogólnokształcące im. Królowej Jadwigi w Inowrocławiu.

W październiku tego samego roku rozpoczęłam studia licencjackie na Wydziale Chemii im. Adama Mickiewicza w Poznaniu na kierunku chemia, specjalność chemia sądowa. W 2018 roku trafiłam do Zakładu Produktów Bioaktywnych, gdzie realizując temat pracy licencjackiej zajmowałam się syntezą czwartorzędowych soli alkiloamoniowych pochodnych kwasów żółciowych. Kontynuując badania pod opieką Pana prof. UAM dr. hab. Tomasza Pospiesznego, w ramach pracy magisterskiej podjęłam się syntezy nowych biokoniugatów steroidowych zawierających pierścienie 1,2,3-triazolowe. W 2021 roku uzyskałam dyplom magisterski za pracę *Synteza, charakterystyka spektroskopowa oraz badania teoretyczne nowego koniugatu steroidowego modyfikowanego pierścieniem 1,2,3-triazolowym*.

Moje zainteresowania tematyką biokoniugatów steroidowych sprawiły, że badania te postanowiłam rozszerzyć podejmując naukę w Szkole Doktorskiej Nauk Ścisłych na Wydziale Chemii Uniwersytetu im. Adama Mickiewicza w Poznaniu w grupie badawczej prof. UAM dr. hab. Tomasza Pospiesznego.

Rezultaty swoich prac zaprezentowałam na dwudziestu jeden konferencjach o zasięgu ogólnopolskim i międzynarodowym (w formie jedenastu komunikatów ustnych i dziesięciu posterów). Zostałam laureatką dwóch prestiżowych nagród za najlepsze wystąpienia ustne.

Jestem współautorką siedmiu artykułów naukowych (w tym sześciu z pierwszym autorstwem, a w trzech jako autor korespondencyjny), gdzie zostały opisane szczegółowo wyniki przeprowadzonych badań nad koniugatami steroidowymi, jak również publikacji powstałej przy współpracy z Katedrą i Zakładem Bromatologii Uniwersytetu im. Karola Marcinkowskiego w Poznaniu. Prace te ukazały się w renomowanych czasopismach z listy filadelfijskiej. Moje osiągnięcia naukowe są poparte imponującymi wynikami, ponieważ sumaryczny Impact Factor wynosi 20,1, natomiast całkowita punktacja ministerialna to 530 pkt.

Poza działalnością naukową aktywnie angażuję się w popularyzację chemii, m.in. poprzez prowadzenie warsztatów edukacyjnych dla uczniów oraz udział w corocznym Poznańskim Festiwalu Nauki i Sztuki. Ponadto, jestem również członkinią Polskiego Towarzystwa Chemicznego.

Nr	Opis
1	Wybrane pochodne steroidów.
2	Struktury pochodnych ergosterolu i cholesterolu.
3	Budowa błony białkowo-lipidowej.
4	Budowa cholestanolu.
5	Epimery cholesterolu.
6	Szkielet steroidowy kwasów żółciowych.
7	Konformacje przestrzenne dekaliny.
8	Rodzaje ułożeń pierścieni A, B, C i D w cząsteczkach steroidów.
9	Micelizacja na przykładzie kwasu cholowego.
10	Skwalamina i jej pochodne (a) oraz model molekularny (b).
11	Możliwe drogi koniugacji związków steroidowych z innymi molekułami.
12	Flukonazol (22) i jego alkinowa (23) pochodna.
13	Koniugaty kwasów żółciowych i flukonazolu.
14	Koniugat kwas żółciowy- β -laktam.
15	Koniugaty o właściwościach antybakteryjnych i antygrzybiczych.
16	Koniugaty steroidowo-tiopurynowe o aktywności przeciwpasożytniczej.
17	Biooniugaty kwas żółciowy-nukleozyd zawierające pierścienie 1,2,3- triazolowe.
18	Pochodne kwasu lithocholowego (49–51) jako inhibitory sialilotransferazy.
19	Biokoniugaty steroidowe powodujące apoptozę komórek raka.
20	Hybrydy kwasów żółciowych i deoksyadenozyny.
21	Potencjał farmakoterapeutyczny opisanych w literaturze koniugatów steroidowych.
22	Fragmety widm ^1H NMR związków (71–73) w zakresie diagnostycznych przesunięć chemicznych.
23	Fragment widma ^{13}C NMR pochodnej kwasu lithocholowego i cholesterolu (71).
24	Eksperymentalne przesunięcia chemiczne (δ_{exp} , CDCl_3) w związku (73) w funkcji izotropowych stałych ekranowania magnetycznego (σ_{calc}) z obliczeń GIAO/B3LYP/6–311G(d,p); (a) protony i (b) atomy węgla-13.
25	Model molekularny pochodnej kwasu cholowego i cholestanolu (76).
26	Interakcje ligandów i sposób wiązania dla związków (73) i (76) w 2Q85. A, C – oznacza ligand (73) (zielony); B, D – oznacza ligand (76) (żółty).

27	Interakcje ligandów i sposób wiązania dla związków (73) i (76) w 1EZF. A, C – oznacza ligand (73) (zielony); B, D – oznacza ligand (76) (żółty).
28	Quasi-podandy kwasów żółciowych zawierające układy 1,2,3-triazolowe.
29	Porównanie sygnałów zaobserwowanych na widmach ^1H NMR di-(82) i tripodstawionej (83) pochodnej kwasu lithocholowego.
30	Porównanie otrzymanych widm FT-IR związku (82) (z grupą N_3 , niebieski) oraz pozostałych związków (83–85) (czerwony).
31	Model molekularny koniugatu kwasu deoksycholowego z pierścieniami 1,2,3-triazolowymi (84).
32	Tworzenie wiązań wodorowych przez ligand (85) z miejscem aktywnymi domeny białka 1HW8.
33	Możliwe wiązania wodorowe ligandu (82) pomiędzy miejscami wiązania domeny białka 1HW8. Energia wiązania wynosi $-8,7$ kcal/mol (średnia energia wiązania wynosi $-8,4$ kcal/mol).
34	Koniugaty steroidowo-pirymidynowe połączone pierścieniami 1,2,3-triazolowymi (93–103).
35	Fragmenty widm ^1H NMR alkinowych pochodnych 2-tiouracylu (89–90).
36	Diagnostyczne sygnały widma ^1H NMR zidentyfikowane dla triazolowych związków kwasu cholowy-uracyl (95) i kwas deoksycholowy-tiouracyl (99).
37	Modele molekularne koniugatu cholesterolu z uracylem (96) i kwasu cholowego z 2-tiouracylem (102).
38	Wiązania wodorowe utworzone pomiędzy koniugatem (97) a miejscem aktywnym syntazy skwalenu (1EZF) określające potencjalną aktywność przeciwgrzybiczną.
39	Wiązania wodorowe utworzone między ligandem pochodnej cholesterolu (96) a domeną białkową bakterii (1KZN) określający potencjalną aktywność przeciwbakteryjną.
40	Potencjalne wiązania wodorowe między ligandem (98) a miejscem aktywnym białka związanego z proliferacją komórek nowotworowych (2H94).

Spis schematów

Nr	Opis
1	Szlak syntezy pierwszorzędowych kwasów żółciowych (CDCA i CA).
2	Transformacje struktury steroidu podczas biosyntezy na przykładzie kwasu cholowego.
3	Wybrane reakcje chemii „click”: cykloaddycja azydkowo-alkinowa (a) i reakcja Dielsa-Aldera (b).
4	Addycja nukleofilowa Michaela (a), synteza azyrydyn (b), epoksydacja (c) oraz dihydroksylacja (d).
5	Reakcje związane z otwarciem pierścienia azyrydyn (a) lub epoksydu (b).
6	Cykloaddycja 1,3-dipolarna (a) oraz cykloaddycja Dielsa-Aldera (b).
7	Reakcje typu „non-aldol”: synteza oksymów (a), hydrazonów (b) oraz układów aromatycznych (c).
8	Regioselektywność reakcji Huisgena zależna od jej warunków.
9	Wybrana reakcja typu katalizy heterogenicznej.
10	Mechanizm reakcji CuAAC.
11	Mechanizm reakcji Mitsunobu.
12	Synteza przebiegająca z inwersją konfiguracji.
13	Halogenoacetoksy podstawienie kwasu cholowego.
14	Wprowadzenie grupy azydkowej w łańcuch boczny steroidu.
15	Modyfikacja grupy karboksylowej z wykorzystaniem glikolu.
16	Przekształcenie kwasu litocholowego w azydek w syntezie inhibitorów α -2,3-sialulotransferazy.
17	Wprowadzenie grupy alkinowej w pozycję C-3 steroidu.
18	Przekształcenie grupy karboksylowej łańcucha bocznego w terminalny alkin.
19	Synteza amidu steroidowego w obecności tritetyloaminy.
20	Synteza 1,2,3-triazolowej pochodnej witaminy D.
21	Otrzymywanie koniugatów kwasów żółciowych i mentolu (28–30).
22	Synteza koniugatów aminocholiny i kwasu cholowego.
23	Synteza steroidowo-urydynowych pochodnych triazolowych.
24	Synteza dendrymerów (tzw. „kieszeni molekularnych”) o właściwościach antynowotworowych.
25	Synteza bromoacetoksy pochodnych kwasów żółciowych (63–65).
26	Synteza azydoacetoksy pochodnych kwasów żółciowych (66–68).
27	Synteza alkinowych pochodnych steroli (69–70).
28	Synteza koniugatów kwasów żółciowych i steroli połączonych pierścieniem 1,2,3-triazolowym (71–76).
29	Wprowadzenie grupy alkinowej w pozycję C-3 szkieletu steroidowego kwasów żółciowych

- 30** Synteza 1,3,5-tris(azydometyleno)benzenu (**81**).
- 31** Synteza dipropargilowych pochodnych uracylu (**88**) i nowoopracowanych dipropargilowych pochodnych 2-tiouracylu (**89–90**).
- 32** Synteza 3 β -azydoctanowych pochodnych steroli (**91–92**).
- 33** Możliwe fragmentacje związków (**89**) i (**90**) podczas analizy EI-MS.

AMACR	racemaza α -metyloacylo-CoA (<i>ang. α-methylacyl-CoA racemase</i>)
BA	kwasy żółciowe (<i>ang. Bile Acids</i>)
BAAT	kwasy żółciowe-CoA:aminokwas N-acylotransferaza
BACS	syntetaza kwasu żółciowego CoA (<i>ang. Bile Acyl-CoA Synthetase</i>)
BCOX	oksydaza rozgałęzionych acylo-CoA (<i>ang. Branched-Chain acyl-CoA Oxidase</i>)
BDP	białko D-bifunkcyjne (<i>ang. D-bifunctional Protein</i>)
BSH	hydrolaza soli żółciowych (<i>ang. Bile Salt Hydrolase</i>)
CA	kwasy cholowe (<i>ang. Cholic Acid</i>)
CDCA	kwasy chenodeoksycholowe (<i>ang. Chenodeoxycholic Acid</i>)
CH25H	25-hydroksylaza cholesterolowa (<i>ang. Cholesterol 25-hydroxylase</i>)
CH27H	27-hydroksylaza cholesterolowa (<i>ang. Cholesterol 27-hydroxylase</i>)
CoA	koenzym A (<i>ang. Coenzyme A</i>)
CTX	ksantomatoza mózgowo-ścięgnowa (<i>ang. Cerebrotendinous Xanthomatosis</i>)
CuAAC	cykloaddycja azydkowo-alkinowa katalizowana miedzią (<i>ang. Cu(I)-Catalyzed Azide-Alkyne Cycloaddition</i>)
CYP7A1	7 α -hydroksylaza cholesterolowa (<i>ang. Cholesterol 7 α-hydroxylase</i>)
CYP7B1	7 α -hydroksylaza oksysterolowa (<i>ang. 25-hydroxycholesterol 7-α-hydroxylase</i>)
CYP8B1	12 α -hydroksylaza sterolowa (<i>ang. Sterol 12-α-hydroxylase</i>)
CYP27A1	27-hydroksylaza sterolowa (<i>ang. Sterol 27-hydroxylase</i>)
CYP46A1	24-hydroksylaza cholesterolowa (<i>ang. Cholesterol 24-hydroxylase</i>)
DBU	1,8-diazabicyklo[5.4.0]undek-7-en (<i>ang. 1,8-Diazabicyclo[5.4.0]undec-7-ene</i>)
DCA	kwasy deoksycholowe (<i>ang. Deoxycholic Acid</i>)
DMF	dimetyloformamid (<i>ang. Dimethylformamide</i>)
DPPA	azydek difenylofosforanu (<i>ang. Diphenylphosphoryl Azide</i>)
EDC*HCL	chlorowodorek 1-etylo-3-(3-dimetyloaminopropyl)karbodiimid (<i>ang. 1-Ethyl-3-(3-dimethylaminopropyl)carbodiimide Hydrochloride</i>)
ESI-MS	spektrometria masowa z jonizacją elektrosprayową (<i>ang. Electrospray Ionisation Mass Spectrometry</i>)
EI-MS	spektrometria masowa z jonizacją elektronową (<i>ang. Electron Ionisation Mass Spectrometry</i>)
FT-IR	spektroskopia w podczerwieni z transformacją Fouriera (<i>ang. Fourier Transform Infrared Spectroscopy</i>)

GIAO	metody orbitali atomowych niezależnych od miernika (ang. <i>Gauge-Independent Atomic Orbital</i>)
GIAO/B3LYP/6-311G	ang. <i>Gauge-Independent Atomic Orbital/ Becke, 3-parameter, Lee-Yang-Parr/ Triple-split valence basis set with six core orbitals and three valence orbitals split into one, one, and one Gaussian functions</i>
HCT116	linia komórek raka jelita grubego (ang. <i>Human Colon Carcinoma 116</i>)
HIV	ludzki wirus niedoboru odporności (ang. <i>Human Immunodeficiency Viruses</i>)
HOF	ciepło tworzenia (ang. <i>Heat of Formation</i>)
HMG-CoA	reduktaza 3-hydroksy-3-metyloglutarylokoenzymu A (ang. <i>3-hydroxy-3-methyl-glutaryl-coenzyme A reductase</i>)
HSD3B7	oksyreduktaza 3 β -hydroksy- Δ 5-C27 steroidowa (ang. <i>Hydroxy-delta-5-steroid dehydrogenase, 3 beta- and steroid delta-isomerase 7</i>)
IC₅₀	połowa maksymalnego stężenia hamującego (ang. <i>Half maximal Inhibitory Concentration</i>)
IMR-32	linia komórek neuroblastoma ludzkiego (nazwa własna)
K562	linia komórek białaczki szpikowej (nazwa własna)
LAH	wodorek litowo-glinowy (ang. <i>Lithium Aluminium Hydride</i>)
LCA	kwas lithocholowy (ang. <i>Lithocholic Acid</i>)
LSD1	demetylaza-1 specyficzna dla lizyny (ang. <i>Lysine-Specific histone Demethylase 1A</i>)
MCF-7	linia komórek raka piersi (ang. <i>Michigan Cancer Foundation-7</i>)
MIC	minimalne stężenie hamujące (ang. <i>Minimal Inhibitory Concentration</i>)
p-TsOH	kwas p-toluenosulfonowy
PASS	przewidywane spektrum aktywności substancji (ang. <i>Prediction of Activity Spectra for Substances</i>)
PA	prawdopodobieństwo wystąpienia danej aktywności biologicznej (ang. <i>Probability „to be Active”</i>)
PI	prawdopodobieństwo braku wystąpienia danej aktywności biologicznej (ang. <i>Probability „to be Inactive”</i>)
PC-3	linia komórek ludzkiego raka prostaty
PDB ID	identyfikator z banku danych o białkach (ang. <i>Protein Data Bank Identifier</i>)
PM5	metoda parametryczna 5 (ang. <i>Parametric Method 5</i>)
SCP_x	białko transportujące sterolu x (ang. <i>Sterol Carrier Protein x</i>)
tert-BuOH	alkohol tert-butyłowy
THF	tetrahydrofuran
VLCS	syntetaza długołańcuchowych acylo-CoA (ang. <i>Very-long-chain acyl-CoA synthetases</i>)

Wstęp

Natura stanowi nieustające źródło aktywnych biologicznie związków heterocyklicznych o zróżnicowanych właściwościach fizycznych, chemicznych i biologicznych. Dostępne środki terapeutyczne często wykazują niestabilność, słabą rozpuszczalność lub oporność gospodarza, co powoduje ich nieskuteczność. Sprzęganie dwóch biologicznie aktywnych cząsteczek niesie wiele korzyści wynikających z braku toksyczności systemowej, zredukowaniu skutków ubocznych oraz, co najważniejsze, zwalczeniu lekooporności komórek docelowych. Biokoniugat to połączenie dwóch lub więcej jednostek strukturalnych o odmiennych właściwościach biologicznych, co sprawia, że utworzona cząsteczka zyskuje spotęgowaną aktywność.

Steroidy obejmują obszerną grupę związków pochodzenia naturalnego występujących we wszystkich komórkach eukariotycznych, wykazujących znaczącą aktywność biologiczną. Istotnie interesujące są kwasy żółciowe oraz β -sterole. Związki te posiadają charakterystyczny dla steroidów sztywny czteropierścieniowy rdzeń cyklopentanoperhydrofenantrenowy o różnym stopniu nienasycenia, właściwości amfipatyczne oraz podatną na modyfikację grupę hydroksylową w pozycji C-3. Ważne są również glikozydy nasercowe (np. scylaren A, digitoksyna) oraz hormony roślinne (np. brassinolid) i zwierzęce (np. estron, testosteron).

Kwasy żółciowe (np. lithocholowy, deoksycholowy, cholowy) stanowią główny składnik żółci, wspomagając emulgowanie tłuszczu, natomiast jako surfaktanty obniżają napięcie powierzchniowe. Charakteryzują się ponadto łańcuchem bocznym zakończonym grupą karboksylową obecną w pozycji C-17 szkieletu steroidowego oraz grupami hydroksylowymi (3α -OH; 3β -OH, 12α -OH; 3α -OH, 7α -OH, 12α -OH) o różnej reaktywności.

Wśród β -steroli zainteresowanie wzbudza cholesterol będący składnikiem zwierzęcych błon komórkowych, zapewniając im sztywność. Jest prekursorem w biosyntezie witaminy D₃, hormonów płciowych oraz kwasów żółciowych.

Fundamentalne znaczenie ma naturalny biokoniugat steroidowy – skwalamina, wyizolowana z komórek kolenia pospolitego (*Squalus acanthias*), wykazująca się właściwościami przeciwko flawiwirusom, HAV, HBV i HCV. Związek ten zastosowano jako antybiotyk działający na szereg szczepów bakterii, jak również w terapii onkologicznej, w leczeniu zwyrodnienia plamki żółtej oka i retinopatii cukrzycowej. Z kolei syntetyczny glikosteroid – deksametazon, cechuje aktywność przeciwzapalna, przeciwalergiczna i immunosupresyjna. Jest niezwykle cenny w leczeniu obrzęku i nowotworu mózgu, a także rekonwalescencji po urazach głowy i zabiegach neurochirurgicznych. Co ciekawe, został zastosowany w łagodzeniu powikłań dróg oddechowych spowodowanych COVID-19.

Ze względu na ogromną różnorodność właściwości biologicznych i fizykochemicznych, steroidy stały się doskonałymi związkami w syntezie organicznej. Transformacje grup funkcyjnych poprzez reakcję estyfikacji prowadzą do wytwarzania nowych pochodnych. Dodatkowe grupy mogą wpływać na zmianę lipofilowości, rozpuszczalności oraz selektywności receptora. Z perspektywy poszukiwania nowych leków steroidowych najistotniejsze jest to, że jako związki lipofilowe mogą skutecznie pokonywać błony komórkowe.

Niezwykle kluczowym aspektem w opracowywaniu ścieżek syntezy dimerycznych i wielkocząsteczkowych biokoniugatów steroidowych jest zastosowanie chemii „click”. Wykorzystanie tej efektywnej, prostej i wysokowydajnej reakcji prowadzi do utworzenia linkerów 1,2,3-triazolowych. Unikalna struktura układów triazolowych pozwala im łatwo

łączyć się z enzymami oraz receptorami w układach biologicznych poprzez wiązania wodorowe, oddziaływania dipol-dipol lub siły van der Waalsa. Wykazują odporność na hydrolizę oraz degradację metaboliczną. Sprzężenie steroidów z pierścieniami 1,2,3-triazolowymi ma szczególne znaczenie z perspektywy aktywności farmakoterapeutycznej nowo powstałej cząsteczki biokoniugatu.

Z danych literaturowych wynika, że drobne przekształcenie struktury steroidowej silnie oddziałuje na układ biologiczny. Ich specyficzny układ przestrzenny pełni kluczową funkcję dla interakcji z receptorami białkowymi. Unikatowe cechy strukturalne i biologiczne steroidów przyczyniły się do wykorzystania ich jako potencjalnego materiału w projektowaniu leków o działaniu przeciwnowotworowym, przeciwdrobnoustrojowym, przeciwzapalnym, jak również o aktywności neuroprotekcji.

Na podstawie pozytywnych wyników dotychczasowych badań wykazano, że związki steroidowe spełniają kluczowe kryteria w kontekście projektowania nowych środków terapeutycznych, a także mogą pełnić funkcję efektywnych nośników leków. Uwzględniając analizę literatury przedmiotu oraz wcześniejsze osiągnięcia badawcze zespołu prof. Pospieszego, celem mojej pracy było opracowanie szlaku syntezy nowych biokoniugatów steroidowych o potencjalnej aktywności biologicznej.

Bazując na obiecujących danych literaturowych zsyntetyzowano 30 nowych pochodnych kwasów żółciowych i steroli. Wykorzystując reakcję chemii „click” wbudowano w strukturę każdej cząsteczki łącznik w postaci pierścienia 1,2,3-triazolowego. Zsyntetyzowane związki można podzielić na trzy grupy: dimery kwasów żółciowych i steroli, quasi-podandy oraz biokoniugaty steroidowo-pirymidynowe. Pełna analiza spektroskopowa i spektrometryczna pozwoliła na potwierdzenie wszystkich otrzymanych struktur. Przeprowadzone obliczenia semiempiryczne wyznaczyły ich energię tworzenia i modele molekularne. Na podstawie badań *in silico* z wykorzystaniem programu PASS oraz wykonanie dokowania molekularnego określono wstępną teoretyczną aktywność biologiczną koniugatów steroidowych. Sprecyzowanie powinowactwa utworzonych cząsteczek do miejsc aktywnych zdefiniowanych domen białkowych uwarunkowało ich obiecujący potencjał przeciwhipercholesterolemiczny, przeciwbakteryjny, przeciwgrzybiczny oraz przeciwnowotworowy.

Rezultaty przeprowadzonych w ramach pracy doktorskiej badań zostały szczegółowo opisane i opublikowane, podobnie jak wyczerpujące artykuły przeglądowe, w renomowanych czasopismach z listy filadelfijskiej.

Część literaturowa

1. Steroidy

Związki pochodzenia naturalnego o zróżnicowanych właściwościach biologicznych zajmują wyjątkowe miejsce w chemii organicznej [1,2]. Szczególnie ważne są steroidy, które zapewniają prawidłowe funkcjonowanie wszystkich komórek organizmów żywych. Biorą udział w przemianach metabolicznych oraz w transporcie wewnątrzkomórkowym [3]. Kwasy żółciowe (np. lithocholowy, deoksycholowy, cholowy) działają jako emulgatory, pomagając w trawieniu i wchłanianiu lipidów oraz kontrolują metabolizm glukozy [4]. Sterole (np. cholesterol, ergosterol, stigmasterol) są komponentami struktury błon komórkowych prokariotów i eukariotów (Rys. 1). Cholesterol (**1**) uczestniczy także w biosyntezie hormonów steroidowych [5]. Te z kolei (np. estrogeny, androgeny) odpowiadają za ekspresję genów, normalną syntezę białek oraz podstawowe działanie regulacyjne i modyfikacyjne tkanek docelowych [6]. Hormony roślinne, takie jak brassinosteroidy (np. brassinolid) kontrolują przebieg procesu fotosyntezy, prawidłowy wzrost roślin oraz działanie innych fitohormonów [7]. Kortykosteroidy odgrywają kluczową rolę w metabolizmie węglowodanów i regulacji stanu zapalnego [6].

Rysunek 1. Wybrane pochodne steroidów.

1.1. Sterole

Alkohole steroidowe jako kluczowe związki lipidowe odgrywają istotną rolę w funkcjonowaniu organizmów żywych. Sterole są integralnymi składnikami błon komórkowych, wpływając na ich strukturę, płynność i funkcje biologiczne. Biorą udział jako główny substrat w biosyntezie ważnych związków bioaktywnych, takich jak hormony steroidowe, witaminy z grupy D lub kwasy żółciowe. Komórki roślinne zwykle zawierają fitosterole, takie jak stigmasterol, β -sitosterol, kampesterol albo fukosterol. W komórkach grzybów można wyróżnić mykosterole – głównie ergosterol będący promotorem ergokalcferolu (**8**), znanego powszechnie jako witamina D₂ (Rys. 2) [8,9]. Jednak największe zainteresowanie wzbudza sterol budujący błony komórkowe u ssaków – cholesterol, dlatego jego właściwości zostaną szerzej omówione.

Rysunek 2. Struktury witamin D – pochodnych ergosterolu i cholesterolu.

1.1.1 Cholesterol

β -sterole podobnie jak pozostałe steroidy kontrolują homeostazę procesów biologicznych zachodzących w celu prawidłowego funkcjonowania organizmu. Ze względu na udział w szeregu przemian metabolicznych cholesterol jest jednym z niewielu związków steroidowych, którego właściwości fizykochemiczne zostały niezwykle dokładnie przeanalizowane. Cholesterol (**1**) należy do zoosteroli, w których jako element budulcowy stabilizuje błonę komórkową, jednocześnie zapewniając jej odpowiednią elastyczność i płynność (Rys. 3).

Rysunek 3. Budowa błony białkowo-lipidowej.

Umożliwia to transport substancji do i z komórki. Ponadto, jego obecność w komórkach mózgu wpływa na utrzymanie struktury neuronów. Cholesterol jest prekursorem w syntezie hormonów steroidowych (np. kortyzolu, aldosteronu), hormonów płciowych (np. testosteronu, progesteronu) i kwasów żółciowych, jak również witaminy D₃ (cholekalcyferolu)

odpowiedzialnej za regulację gospodarki wapniowo-fosforanowej. Natomiast jako kluczowy składnik mieliny (osłonki otaczającej włókna nerwowe) ma znaczący udział w szybkim i skutecznym przesyłaniu sygnałów nerwowych [10].

Cholestanol (5 α -dihydrocholesterol) (9) jest nasyconą formą cholesterolu, a jego struktura różni się wyłącznie zredukowanym wiązaniem podwójnym w pozycji C-5 i C-6 w cząsteczce (Rys. 4). Głównie powstaje w wyniku jego przemian metabolicznych. W organizmie występuje w śladowych ilościach, ale jego obecność ma diagnostyczne znaczenie w przypadku rzadkich schorzeń. Podwyższony poziom cholestanolu może być związany z chorobą ksantomatozą mózgowo-ścięgnistą (CTX). To zaburzenie metaboliczne spowodowane nieprawidłową przemianą kwasów żółciowych prowadzącą do gromadzenia cholestanolu w organizmie, a w konsekwencji do postawiania złogów w ścięgnach, uszkodzeniem układu nerwowego bądź zaćmą [11,12].

Rysunek 4. Budowa cholestanolu.

1.1.2. Stereochemia cholesterolu

Unikalna struktura przestrzenna cholesterolu, wynikająca ze stereochemii jest kluczowa dla jego funkcjonalności. Będąc steroidem niezmiennie posiada podstawowy element ich budowy – szkielet cyklopentano[α]perhydrofenantrenu. Sprzężone pierścienie tworzą płaską cząsteczkę z konfiguracją *cis* pierścieni B/C oraz *trans* C/D. Zoosterol cechuje 8 centrów stereogenicznych determinujących charakterystyczne ułożenie grup funkcyjnych i łańcucha bocznego. Z perspektywy syntezy organicznej ważna jest ekwatorialna grupa hydroksylowa znajdująca się w konfiguracji β (nad płaszczyznę pierścienia A) przy atomie węgla C-3 (Rys. 5). Nadaje cząsteczce amfipatycznego charakteru oraz umożliwia jej modyfikację. Natomiast obecność rozgałęzionego łańcucha bocznego przy atomie węgla C-17 wpływa na zdolność sterolu do wbudowywania się w błony komórkowe. Co więcej, cholesterol występuje w organizmach jako jeden enancjomer, dzięki czemu łatwo wchodzi w interakcje z innymi biomolekułami. Przestrzenna budowa cholesterolu ułatwia jego dopasowywanie się do fosfolipidów w dwuwarstwie i warunkuje transformację struktury [13,14].

Rysunek 5. Epimery cholesterolu.

1.2. Kwasy żółciowe

1.2.1. Charakterystyka i znaczenie biologiczne kwasów żółciowych

Kwasy żółciowe jako cząsteczki aktywne biologicznie są wytwarzane w organizmach wszystkich kręgowców w wyniku przemian metabolicznych cholesterolu [15]. Obecność 24-węglowej struktury spowodowała, że powszechnie u ssaków noszą miano kwasów żółciowych C24 (Rys. 6). Wynika to z obecności trzech sześcioczłonowych pierścieni A, B i C, pięcioczłonowego pierścienia D oraz pięciowęglowego łańcucha bocznego z grupą karboksylową w pozycji C-24 [16,17]. Kwas lithocholowy (3 α -hydroksycholanowy) (**10**), kwas deoksycholowy (kwas 3 α ,12 α -dihydroksycholanowy) (**11**) i kwas cholowy (3 α ,7 α ,12 α -trihydroksycholanowy) (**12**) wzbudzają największe zainteresowanie jako reagenty w syntezie organicznej [18–20].

Nr	R ¹	R ²	R ³	Nazwa
10	H	H	OH	Kwas lithocholowy
11	H	OH	OH	Kwas deoksycholowy
12	OH	OH	OH	Kwas cholowy
13	OH	H	OH	Kwas chenodeoksycholowy
14	OH	H	NHCH ₂ CO ₂ H	Kwas glikochenodeoksycholowy
15	OH	H	NHCH ₂ CH ₂ SO ₃ H	Kwas taurochenodeoksycholowy
16	OH	OH	NHCH ₂ CO ₂ H	Kwas glikocholowy
17	OH	OH	NHCH ₂ CH ₂ SO ₃ H	Kwas taurocholowy

Rysunek 6. Szkielet steroidowy kwasów żółciowych.

Kwasy żółciowe stanowią główny składnik żółci, gdzie występują w formie sprzężonych soli z glicyną (75 %) lub tauryną (25 %) [21]. Jednocześnie zwiększa to ich rozpuszczalność w wodzie w warunkach fizjologicznych [22]. Około 95% kwasów żółciowych

jest wchłaniane w jelicie, następnie trafia z krwią do wątroby i ponownie do żółci, by wrócić do jelita (tzw. krążenie jelitowo-wątrobowe). Pozostałe 5% jest wydalone, a straty uzupełnia synteza *de novo* w wątrobie [23–25].

Główne właściwości fizjologiczne kwasów żółciowych obejmują transport lipidów poprzez ich solubilizację oraz usuwanie cholesterolu do przewodu pokarmowego, skąd jego wchłanianie jest ograniczone. Funkcje te wynikają z ich amfipatycznego charakteru, który wiąże się z obecnością hydrofilowej i hydrofobowej powierzchni [26–28]. Z kolei koniugacja z kwasami tłuszczowymi, cholesterolem i monoglicerydami BA prowadzi do ich micelizacji i umożliwia emulgowanie tłuszczu [29,30]. Tworzenie miceli powoduje zwiększenie powierzchni tłuszczu narażonej na działanie lipaz trzustkowych, co umożliwia bardziej efektywne trawienie i wchłanianie lipidów przez komórki jelita cienkiego [31]. Micele powstałe z udziałem kwasów żółciowych wspomagają również rozpuszczanie i absorpcję witamin rozpuszczalnych w tłuszczach [32]. Biorąc pod uwagę ogólny udział BA w krążeniu jelitowo-wątrobowym ich zadania ograniczają się przede wszystkim do: regulacji homeostazy cholesterolu, zapobiegania tworzeniu się kamieni żółciowych i nerkowych, działania przeciwdrobnoustrojowego oraz funkcji regulacyjnych. Udowodniono, że ich receptory są obecne w większości narządów i tkanek, stąd mogą pełnić rolę cząsteczek sygnałowych. Kwasy żółciowe uczestniczą w proliferacji komórek, reakcjach detoksykacji i regulacji układu odpornościowego [33–37].

1.2.2. Stereochemia kwasów żółciowych

Szkielet steroidowy BA posiada 7 chiralnych atomów węgla (tj. C-5, C-8, C-9, C-10, C-13, C-14, C-17), co wskazuje na 128 stereoizomerów. Jednak surowe ograniczenia związane z kondensacją pierścieni cyklicznych wpłynęły na istnienie tylko kilku z nich. Pierścienie A/B naturalnych steroidów przyjmują konformację przestrzenną *cis* lub *trans*. Jest to charakterystyczna cecha układów sześć- i pięcioczłonowych, co potwierdza rotacja pomiędzy strukturami *cis* i *trans*-dekaliny (Rys. 7) [38,39].

Rysunek 7. Konformacje przestrzenne dekaliny.

Sposób ułożenia się skondensowanych pierścieni A/B podczas transformacji determinuje występowanie dwóch rodzajów szeregów w konfiguracji przestrzennej steroidów:

- *allo* – typowy w przypadku większości steroli. Charakterystyczny jak w *trans*-dekalinie układ pierścieni A/B; płaska cząsteczka, w której grupa metylowa CH₃-19 i atom wodoru występują naprzeciw siebie, a dodatkowo można utworzyć dwie konformacje

krzesłowe. Sztywna struktura tego typu układu ogranicza wydajność syntez prowadzących do otrzymania niekorzystnej energetycznie konformacji łódkowej (Rys. 8a).

- normalny – preferowany w przypadku kwasów żółciowych. Podobny jak w *cis*-dekalinie układ pierścieni A/B, grupa metylowa CH₃-19 i atom wodoru występują po jednej stronie pierścienia. Specyficzna i stabilna wykrzywiona struktura decyduje o pozostaniu wysoko korzystnej energetycznie konformacji krzesłkowej bez względu na typ syntezy (Rys. 8b) [40].

Rysunek 8. Rodzaje ułożeń pierścieni A, B, C i D w cząsteczkach steroidów.

Zgodnie z tym założeniem u wyższych kręgowców szkielet steroidowy kwasów żółciowych przyjmuje konformację *cis* pierścieni A/B (Rys. 8c). Charakterystyczne dla ich struktury są również: czystość enancjomeryczna, sztywny układ pierścieni alicyklicznych, 11 chiralnych atomów węgla, zróżnicowane chemicznie grupy hydroksylowe w pozycjach C-3 α , C-7 α , C-12 α oraz alifatyczny łańcuch przy atomie węgla C-17 zakończony grupą karboksylową [41,42]. Wymienione dwie ostatnie cechy nadają im szczególnych właściwości fizykochemicznych, dzięki którym stały się materiałem budulcowym w projektowaniu nowych cząsteczek będących antybiotykami, sztucznymi kanałami jonowymi, receptorami jonowymi, nośnikami leków oraz surfaktantami [43–47].

Amfipatyczny charakter kwasów żółciowych wynika z hydrofilowej i hydrofobowej części ich struktury. Grupy hydroksylowe i karboksylowy łańcuch boczny tworzą tzw. α -ścianę (hydrofilową) (Rys. 9). Z kolei grupy metylowe C-18 i C-19 nadają im hydrofobowego charakteru, dając tzw. β -ścianę [48]. Wpływa to na wysoką aktywność powierzchniową kwasów żółciowych, dzięki której mogą tworzyć w roztworach wodnych małe agregaty lub micelle mniejsze niż 10 monomerów [49,50].

Rysunek 9. Micelizacja na przykładzie kwasu cholowego [P3].

Liczba i rozkład różnych reaktywnie grup hydroksylowych decyduje o podatności kwasów na szereg reakcji, takich jak acetylowanie, estryfikacja, hydroliza bądź redukcja. Ze względu na położenie ekwatorialną grupę 3α -OH łatwo zmodyfikować, co jest najbardziej utrudnione w przypadku grupy 12α -OH z powodu dużego zatłoczenia sterycznego w jej otoczeniu [51].

1.2.3. Biosynteza kwasów żółciowych

Kwasy żółciowe są produkowane w wątrobie z cholesterolu jako pierwszorzędowe kwasy żółciowe, przy udziale 17 enzymów katalizujących 17 różnych reakcji. U ssaków proces ten odbywa się w cytozolu, siateczce śródplazmatycznej (mikrosomach), mitochondriach i peroksysomach (Schemat 1). Jednocześnie ma on ogromne znaczenie dla kontrolowania homeostazy cholesterolu, ponieważ odpowiada za katabolizm połowy jego dobowej produkcji [52,53].

Istnieją dwa szlaki syntezy kwasów żółciowych: klasyczny (główny, neutralny) i alternatywny (kwasowy). Pierwszy z nich determinuje produkcję 90 % kwasów żółciowych u osób dorosłych, natomiast drugi pozostałych 10 % i przeważa u noworodków oraz pacjentów z chorobami wątroby [54].

Główna ścieżka syntezy rozpoczyna się od hydroksylacji pierścienia sterolowego w pozycji C-7 obecności 7α -hydroksylazy cholesterolowej (CYP7A1) (Schemat 2). Utworzony produkt pośredni jest następnie atakowany przez 27-hydroksylazę sterolową (CYP27), która modyfikuje łańcuch boczny, dając kwas chenodeoksycholowy. W celu syntezy kwasu cholowego tę transformację poprzedza jeszcze hydroksylacja w pozycji C-12 katalizowana przez 12α -hydroksylazę (CY8B1). W tym przypadku szybkość procesu metabolicznego zależy od aktywności enzymu CYP7A1, a aktywność enzymu CY8B1 wpływa na hydrofilowość steroidu i reguluje stosunek produkcji dwóch kwasów pierwotnych (CA i CDCA) [55].

AKR1C4 – dehydrogenaza 3 α -hydroksysteroidowa; AKR1D1 – 5 β -reduktaza Δ 4-3-oksosteroidowa; AMACR – racemaza α -metyloacylo-CoA; BAAT – Kwas żółciowy-CoA:aminokwas *N*-acylotransferaza; BACS – syntetaza kwasu żółciowego CoA; BCOX – oksydaza rozgałęzionych acylo-CoA; BDP – białko D-bifunkcyjne; CA – kwas cholowy; CDCA – kwas chenodeoksycholowy; CYP27A1 – 27-hydroksylaza sterolowa; CYP7A1 – 7 α -hydroksylaza cholesterolowa; CYP7B1 – 7 α -hydroksylaza oksysterolowa; DHCA – kwas 3 α ,7 α -dihydroksycholestanowy; HSD3B7 – oksyreduktaza 3 β -hydroksy- Δ 5-C27 steroidowa; SCPx – białko transportujące sterolu x; THCA – kwas 3 α ,7 α ,12 α -trihydroksycholestanowy; VLCS – syntetaza długolącuchowych acylo-CoA

Schemat 1. Szlak syntezy pierwszorzędowych kwasów żółciowych (CDCA i CA).

Alternatywny szlak w przeciwieństwie do klasycznego zakłada syntezę głównie CDCA. Na początku odbywa się hydroksylacja łańcucha bocznego cholesterolu na końcu C-27 przez enzym CYP27. Następnie aktywność 7 α -hydroksylazy oksysterolowej (CYP7B1) prowadzi do dalszych przekształceń 27 α -hydroksysterolu do kwasu 3 β ,7 α -dihydroksy-5-cholestenowego. Kolejne modyfikacje tego związku dają w konsekwencji kwas CDCA. Warto zauważyć, że hydroksysterole mogą być również wytwarzane w organach innych niż wątroba, takich jak płuca lub mózg, jednak przetransportowanie do niej nie wyklucza ich udziału w kwasowej ścieżce biosyntezy BA. Alternatywna ścieżka chroni osoby ze schorzeniami wątroby przed hipercholesterolemią [56,57].

W wyniku działania dwóch enzymów, takich jak syntaza kwasu żółciowego-CoA i *N*-acylotransferaza kwasu żółciowego-CoA, kwas cholowy i chenodeoksycholowy ulegają sprzężeniu z tauryną i glicyną, po którym wędrują do żółci, gdzie są przechowywane w pęcherzykach żółciowych. Utworzone sole cechuje wyższa hydrofilowość, kwasowość oraz mniejsza cytotoksyczność [58,59].

Schemat 2. Transformacje struktury cholesterolu podczas biosyntezy na przykładzie kwasu cholowego.

Większość (około 95%) kwasów żółciowych po emulgowaniu tłuszczu w jelicie cienkim zostaje wtórnie wchłonięta przez odcinek jelita krętego i przeniesiona do wątroby. Pozostałe 5 % ulega biotransformacji przez bakterie jelitowe, w wyniku której dehydoksylacja odpowiednio CA i CDCA prowadzi do powstania drugorzędowych kwasów żółciowych: kwasu deoksycholowego i kwasu lithocholowego. Aktywność bakteryjnej hydrolazy soli żółciowych (BSH) przy udziale bakterii z rodzaju *Bacteroides*, *Clostridium*, *Bifidobacterium* oraz *Lactobacillus* powoduje dekonjugację. W kolejny etap zaangażowana jest bakteryjna 7 α -dehidroksylaza, która eliminuje grupę 7-OH z kwasów CA i CDCA, co z kolei prowadzi do utworzenia odpowiednio kwasów DCA i LCA [60].

Kwas lithocholowy wykazuje słabą rozpuszczalność w wodzie i toksyczność. Niemalże w całości jest wydalany z kałem, ale około 2 % po powrocie do wątroby ulega przemianom w celu usunięcia z moczem. Natomiast kwas deoksycholowy cechuje bakteriobójczość, dzięki której może zapobiegać przerostowi mikroflory w jelicie. Z drugiej jednak strony kwasy wtórne są promotorami zmian patologicznych jelita grubego, często prowadzących do nowotworu [61].

1.3. Znaczenie aktywności biologicznej steroidów

Skwalamina (18) to jeden z kluczowych naturalnych koniugatów steroidowo-poliaminowych o monumentalnym znaczeniu dla chemii związków bioaktywnych (Rys. 10). Została wyizolowana z wątroby kolenia pospolitego (*Squalus acanthias*), u którego silnie wspiera układ odpornościowy przed chorobami nowotworowymi i wirusowymi [62]. Ten aminosterolowy antybiotyk, będący koniugatem spermidyny i 24-siarczanu 7 α ,24 ζ -dihydroksy-5 α -cholestanu, rozpuszcza się w wodzie dzięki hydrofobowemu szkieletowi steroidowemu, grupie hydroksylowej i aminowej [63]. Stereochemia i ładunek związku umożliwiają przenikanie przez błonę komórkową, transportując białka związane elektrostatycznie z błoną cytoplazmatyczną [64]. Skwalamina hamuje agregację α -synukleiny, zapobiegając chorobie Parkinsona, ograniczając toksyczne agregaty i neutralizując już istniejące [65]. Wykazuje aktywność biobójczą wobec szerokiego spektrum mikroorganizmów (w tym wirusa HIV). Spowalnia również rozwój nowotworów mózgu, wspierając działanie cytotoksycznych leków przeciwnowotworowych w raku płuc, sutka, jajnika i prostaty [66].

(a)

(b)

Rysunek 10. Skwalamina i jej pochodne (a) oraz model molekularny (b).

Zróźnicowanie właściwości biologicznych i fizykochemicznych związków naturalnych zadecydowało o wykorzystaniu ich w syntezie bioorganicznej. Przekształcenie grup funkcyjnych w wyniku estryfikacji, eteryfikacji, utlenienia, redukcji bądź amidowania

prowadzi do utworzenia nowych pochodnych o ulepszonych właściwościach farmakokinetycznych (lipofilowości, rozpuszczalności) i farmakodynamicznych (inna selektywność receptora) (Rys. 11). Charakter lipofilowy steroidów pozwala im na pokonywanie barier biologicznych, jednak łatwo może ulec zmianie w wyniku wprowadzenia bardziej polarnych grup funkcyjnych, co znacznie zwiększy ich rozprzowanie i czas działania w organizmie. Sztywny szkielet steroidowy umożliwia im penetrację komórki oraz wiązanie z receptorem hormonalnym lub białkowym. Struktura cząsteczki i cechy biologiczne steroidów wpłynęły na wykorzystanie ich w projektowaniu leków o aktywności przeciwnowotworowej, przeciwbakteryjnej, przeciwgrzybiczej, przeciwwirusowej lub przeciwzakrzepowej oraz stosowanych w leczeniu choroby Alzheimer'a. Ponadto, znalazły zastosowanie również w innych dziedzinach jako receptory molekularne, quasi-podandy, szczypce molekularne czy receptory wychytujące kationy i aniony [67–70].

Rysunek 11. Możliwe drogi sprzęgania związków steroidowych z innymi molekułami [P1].

2. Chemia „click”

W 2001 roku profesor Sharpless i współpracownicy zaproponowali rewolucyjną metodę projektowania i syntezy nowych złożonych cząsteczek. Chemia „click” (chemia „kliknięć”) odnosi się do wysoko wydajnych reakcji chemicznych, które są proste w wykonaniu, szybkie, selektywne i nie dają produktów ubocznych. Odpowiednio zaprojektowane fragmenty molekularne łatwo ulegają połączeniu w precyzyjny sposób [71,72].

Podstawowe zasady chemii „click” obejmują koncepcje takie jak modularność, wysoka wydajność oraz efektywność atomowa, która z kolei jest kluczowa dla reguł tzw. „zielonej chemii”. Ze względu na te cechy metoda ta znalazła szerokie zastosowanie głównie w dziedzinach związanych z farmaceutykami, chemią medyczną i materiałową oraz biologią chemiczną [72]. Wśród najbardziej znanych reakcji opierających się na schemacie „click” należą cykloaddycja azydkowo-alkinowa katalizowana miedzią (CuAAC – *Copper-Catalyzed Azide-Alkyne Cycloaddition*), reakcje tiol-enowe oraz reakcje Dielsa-Aldera (Schemat 3) [74].

Schemat 3. Wybrane reakcje chemii „click”: cykloaddycja azydkowo-alkinowa (a) i reakcja Dielsa-Aldera (b).

2.1. Typy reakcji chemii „click”

Istnieją przemiany chemiczne, które wymagają określonych warunków termodynamicznych, wskutek których zostanie utworzony tylko jeden produkt końcowy.

Jedną z podstawowych reakcji cyklicznych chemii „click”, w której tworzy się wiązanie atom węgla–heteroatom jest cykloaddycja [4+2], zwana również reakcją Dielsa-Aldera (Schemat 3b). Z kolei cykloaddycja 1,3-dipolarna dąży do utworzenia nowych koniugatów heterocyklicznych złożonych z wielu zróżnicowanych pięcio- i/lub sześcioczłonowych pierścieni, gdzie synteza rozpoczyna się od sprzężenia dwóch nienasyconych związków (Schemat 3a) [75].

Wyróżnia się cztery najważniejsze rodzaje przekształceń przebiegające zgodnie z zasadami chemii „click”:

(1) addycja do wielokrotnego wiązania węgiel–węgiel:

- addycja Michaela (Schemat 4a);
- synteza azyrydyn (Schemat 4b);
- epoksydacja (Schemat 4c);
- dihydroksylacja (Schemat 4d);

Schemat 4. Addycja nukleofilowa Michaela (a), synteza azyrydyn (b), epoksydacja (c) oraz dihydroksylacja (d).

(2) reakcje substytucji nukleofilowej:

- szczególnie transformacja, w wyniku której pęka wiązanie, co skutkuje otwarciem pierścienia w układach heterocyklicznych związków elektrofilowych, takich jak azyrydyny, epoksydy, cykliczne siarczany;

Schemat 5. Reakcje związane z otwarciem pierścienia azyrydyny (a) lub epoksydu (b).

(3) cykloaddycja związków nienasyconych:

- cykloaddycja 1,3-dipolarna, w tym cykloaddycja Dielsa-Aldera;

Schemat 6. Cykloaddycja 1,3-dipolarna (a) oraz cykloaddycja Dielsa-Aldera (b).

(4) modyfikacje związków karbonylowych typu „non-aldol”:

- otrzymywanie eterów oksymowych, hydrazonów oraz aromatycznych układów heterocyklicznych.

Schemat 7. Reakcje typu „non-aldol”: synteza oksymów (a), hydrazonów (b) oraz układów aromatycznych (c).

Warto zauważyć, że wszystkie syntezy „click” charakteryzuje wysoka aktywność termodynamiczna, gdzie konieczny nakład energii jest wyższy niż 20 kcal/mol.

2.2. Cykloaddycja azydkowo-alkinowa katalizowana jonami miedzi (CuAAC)

Fundamentalną reakcją chemii „click” jest 1,3-dipolarna cykloaddycja azydkowo-alkinowa katalizowana jonami miedzi, znana jako reakcja Huisgena. Ten rodzaj reakcji pericyklicznej stosuje 1,3-dipol oraz dipolarofil jako substraty wyjściowe. Pierwszy z nich wskazuje na związek zbudowany dwubiegunowo, tj. składający się z elektrofilowego i nukleofilowego końca (taki jak azydek, ozon, diazometan). Natomiast dipolarofil charakteryzuje się pewnym stopniem nienasycenia spowodowanym deficytem elektronów. Wskutek sprzężenia terminalnych alkinów z azydkami w obecności miedzi, dzięki któremu dochodzi do cyklicznego przejścia elektronów π powstaje zwykle jeden produkt posiadający co najmniej dwa stabilizujące układ pierścieni wiązania [76,77].

Klasyczna reakcja Huisgena przebiegała w podwyższonej temperaturze, na skutek czego utworzony produkt był mieszaniną 1,4- i 1,5-dipodstawionych 1,2,3-triazoli. Kluczowe jest zastosowanie jonów miedzi(I) jako katalizatora, wskutek czego reakcja jest regioselektywna, wydajniejsza oraz blisko 10^6 szybsza niż przemiana przeprowadzona

wyłącznie w wyższej temperaturze (Schemat 8). Utworzony 1,4-dipodstawiony 1,2,3-triazol cechuje stabilność i brak toksyczności, natomiast użyte substraty najczęściej brak reaktywności w stosunku do grup funkcyjnych molekuly, jak również brak wpływu grup azydkowych i alkinowych na jej bioaktywność [78].

Schemat 8. Regioselektywność reakcji Huisgena zależna od jej warunków.

2.2.1. Sposoby wprowadzenia jonów $Cu(I)$

Dostarczenie do mieszaniny reakcyjnej jonów miedzi(I) decyduje o prawidłowym kierunku reakcji. Zastosowanie warunków wodnych (np. układu *tert*-butanol/woda) wskazuje na technikę *in situ*, w której jony $Cu(I)$ uzyskuje się z pięciowodnego siarczanu(VI) miedzi(II) albo octanu miedzi(II), redukując te sole odpowiednimi odczynnikami, takimi jak askorbinian sodu, miedź metaliczna, hydrazyna lub tris(2-karboksyetylo)fosfina (jak na Schemacie 3a).

W układzie niepolarnym oraz wykorzystując kompleksy soli miedzi z nadmiarem zasady (np. trietyloaminy) zostanie utworzony acetylenek miedzi. Jony miedzi(I) można pozyskać również stosując niektóre halogenki miedzi (CuI , $CuBr$), tlenki miedzi(I) i (II) oraz nanoklastery Au_4Cu_4 [75,79–81].

Z kolei kataliza heterogeniczna należy do wydajnych i tanich metod syntezy 1,4-dipodstawionych pochodnych 1,2,3-triazoli (Schemat 9b). Katalizator miedziowy znajduje się na nośniku węglowym (Cu/C). Zakonserwowany wodnym roztworem azotanu(V) miedzi(II) węgiel drzewny poddaje się destylacji wody i suszeniu, w wyniku czego tlenki miedzi(I) i (II) pokrywają powierzchnię katalizatora (Schemat 9a). W tego typu układzie można łatwo usunąć reduktor i katalizator bądź wygodnie wybrać rozpuszczalnik, jak również zmienić warunki reakcji dodając trietyloaminę lub podwyższając temperaturę [82].

Schemat 9. Wybrana reakcja typu katalizy heterogenicznej.

2.2.2. Mechanizm reakcji CuAAC

Cykloadycja azydkowo-alkinowa katalizowana jonami miedzi(I) jest efektywnym procesem charakteryzującym się kilkuetapowym mechanizmem (Schemat 10). Jony miedzi(I) pełnią kluczową rolę w aktywacji alkinu, umożliwiając utworzenie trójczołowego kompleksu z azydkiem. W pierwszym etapie następuje koordynacja jonów Cu(I) do wiązania potrójnego alkinu, zwiększając jego elektrofilowość (A). Aktywowany acetylenek miedzi zostaje zaatakowany przez azydek, tworząc przejściowy kompleks metaloorganiczny (B). Następnie reorganizacja wiązań prowadzi do zamknięcia pięcioczłonowego pierścienia, dając strukturę 1,2,3-triazolu (C, D i E). Uzyskany 1,4-podstawiony 1,2,3-triazol charakteryzuje wysoka odporność chemiczna i termiczna, a jedynym produktem ubocznym jest cząsteczka wody, co czyni reakcję zgodną z zasadami zielonej chemii [83,84].

Schemat 10. Mechanizm reakcji CuAAC.

Ze względu na wydajność sięgającą często 100% oraz chemoselektywność wynikającą z eliminacji izomerycznych związków ubocznych, reakcja ta ma przełomowe znaczenie w syntezie organicznej. Dodatkowo, zwykle przeprowadzana jest w temperaturze nieprzekraczającej 65°C, co minimalizuje ryzyko związane z degradacją substratów. Zastosowanie warunków wodnych zwiększa jej ekologiczność. Prostota, niezawodność i minimalne wymogi oczyszczania sprawiły, że stała się filarem chemii „click”, znajdując zastosowanie w syntezie leków, modyfikacji polimerów oraz w chemii biomolekularnej (znakowanie białek i kwasów nukleinowych) [85].

2.3. 1,2,3-triazolowe koniugaty steroidowe

Układy 1,2,3-triazolowe to pięciocłonowe krystaliczne związki heterocykliczne. Cechuje je rozpuszczalność w wodzie oraz wysoka odporność na stres oksydacyjny/redukujący, hydrolizę i degradację metaboliczną. Ich wyjątkową właściwością jest możliwość wiązania się z receptorami lub enzymami wskutek oddziaływań takich jak wiązania wodorowe, siły van der Waalsa lub interakcje hydrofobowe [86]. Ze względu na niepodatność tych wiązań na rozszczepienie przez proteazy są one porównywane do wiązań peptydowych. Pochodne 1,2,3-triazolowe wyróżnia doskonała aktywność biologiczna, szczególnie ważna w leczeniu chorób związanych: z nowotworami, zakażeniami (przez pasożyty, bakterie, grzyby, wirusy), nadciśnieniem tętniczym, depresją, cukrzycą, ośrodkowym układem nerwowym oraz chorobą Alzheimera [87–90].

2.3.1. Wprowadzenie grupy azydkowej do szkieletu steroidowego

Zaprojektowano i opisano wiele ścieżek syntetycznych przekształcających odpowiednie grupy funkcyjne szkieletu steroidowego w grupę azydkową. Najczęściej stosowaną metodą jest modyfikacja grupy hydroksylowej w pochodną tosyłową lub mesyłową. Następnie w wyniku reakcji substytucji nukleofilowej anion azydkowy oddziałuje na elektrofil [91]. W zależności od konfiguracji przestrzennej wyróżnia się dwa różne mechanizmy tej reakcji: bez inwersji lub z inwersją konfiguracji produktu końcowego.

2.3.1.1. Reakcja Mitsunobu – bez inwersji konfiguracji

Pierwszy z dostępnych rozwiązań zakłada, że azydkowa pochodna przyjmuje stereochemię alkoholu. W celu dokonania początkowej inwersji konfiguracji związku przeprowadza się reakcję Mitsunobu (Schemat 11). Otrzymana struktura mesyłowa jest podatna na atak nukleofilowego azydku sodu, co w konsekwencji daje związek azydku z zachowaną konfiguracją przyjętą wcześniej przez alkohol [92].

**Schemat 11.** Mechanizm reakcji Mitsunobu.

2.3.1.2. Reakcja z inwersją konfiguracji

Druga metoda zakłada otrzymanie pochodnej steroidowej o konfiguracji przeciwnej względem wyjściowego alkoholu (Schemat 12). W tym celu należy zastosować inne odczynniki wprowadzające grupę mesylową niż te obecne w reakcji Mitsunobu. Opracowano również syntezę, gdzie produktem pośrednim jest pochodna tosyłowa, która ulegając podobnym reakcjom substytucji nukleofilowej zostaje przekształcona w azydek [93].

**Schemat 12.** Synteza przebiegająca z inwersją konfiguracji.

Istnieje również ścieżka wykorzystująca halogenoacetoksy podstawione pochodne steroidów. Wzbogacenie szkieletu steroidowego w ugrupowanie azydkowe opiera się na substytucji atomu halogenu (najczęściej bromu). Reakcja ta jest zwykle stosowana w przypadku kwasów żółciowych (Schemat 13) [94,95].

Schemat 13. Halogenoacetoksy podstawienie kwasu cholowego.

Z kolei modyfikacje łańcucha bocznego kwasów żółciowych polegają głównie na reakcjach zmierzających do zredukowania grupy karboksylowej do grupy hydroksylowej. Utworzony alkohol można przekształcić ponownie w pochodną mesylową, która następnie ulega sprzężeniu z azydkiem sodu (Schemat 14) [96].

Schemat 14. Wprowadzenie grupy azydkowej w łańcuch boczny steroidu.

Zaprojektowano również metodę rozpoczynającą się od transformacji grupy karboksylowej łańcucha bocznego w monoester glikolu etylenowego. W wyniku mesylowania grupy hydroksylowej glikolu, a w kolejnym etapie reakcji powstałego związku przejściowego z azydkiem sodu otrzymano strukturę pochodnej steroidowej z wbudowaną grupą azydkową (Schemat 15) [97].

Schemat 15. Modyfikacja grupy karboksylowej z wykorzystaniem glikolu.

Grupa badawcza kierowana przez Zhu dążyła do syntezy inhibitorów α -2,3-sialulotransferazy. Seria przeprowadzonych reakcji chemicznych wzbogaciła łańcuch boczny kwasu litcholowego o grupę azydkową (Schemat 16). Proces rozpoczęto od estryfikacji steroidu, a następnie uzyskany litcholan metylu zredukowano do alkoholu (przy użyciu LAH). W kolejnym etapie działanie azydku difenylofosforanu (DPPA) i DBU na alkohol przekształciło grupę hydroksylową w łańcuchu bocznym w grupę difenylofosforanu. Uzyskany związek został przekonwertowany w azydek steroidowy, wykorzystując nadmiar azydku sodu, eter koronowy i katalityczne ilości jodku tetrabutylamoniowego [98].

Schemat 16. Przekształcenie kwasu litcholowego w azydek w syntezie inhibitorów α -2,3-sialulotransferazy

2.3.2. Wprowadzenie grupy alkinowej do szkieletu steroidu

Opisano kilka sposobów wprowadzających terminalną grupę alkinową w cząsteczkę steroidu, jednak najbardziej znane jest zastosowanie glikolu etylenowego (Schemat 17) [99].

Schemat 17. Wprowadzenie grupy alkinowej w pozycję C-3 steroidu.

Natomiast grupa karboksylowa łańcucha bocznego kwasów żółciowych ulega łatwo reakcji estryfikacji z użyciem alkoholu propargilowego (Schemat 18) [100,101].

Schemat 18. Przekształcenie grupy karboksylowej łańcucha bocznego w terminalny alkin.

Dobór odpowiedniego katalizatora syntezy znacząco wpływa na jej kierunek. W obecności EDC*HCl istnieją dwie drogi reakcji. Ester z wiązaniem potrójnym będzie produktem końcowym reakcji, jeśli wezmą w niej udział tylko i wyłącznie kwas żółciowy i alkohol propargilowy. Wprowadzenie do układu reakcyjnej propargiloaminy skutkuje powstaniem amidu (Schemat 19) [102].

Schemat 19. Synteza amidu steroidowego w obecności tritetyloaminy.

Suh zaproponował metodę syntezy 1,2,3-triazolowych koniugatów witaminy D, w której wykorzystał terminalny alkin podstawiony grupą trimetylosilolową (Schemat 20). Powstały w wyniku reakcji związek (A) został poddany serii przemian chemicznych, prowadzących do uzyskania 1,2,3-triazolowej pochodnej witaminy D [103].

Schemat 20. Synteza 1,2,3-triazolowej pochodnej witaminy D.

2.4. Koniugaty steroidowo-triazolowe o aktywności biologicznej

Kwasy żółciowe, jak już wymieniono, wyróżniają się sztywnym rdzeniem steroidowym, wysoką aktywnością grup funkcyjnych oraz wyjątkowymi właściwościami amfifilowymi. Te unikalne cechy decydują o ich ogromnej roli jako materiału biologicznego do syntez związków o potencjalnym zastosowaniu w przemyśle farmakoterapeutycznym. Są prekursorami do otrzymywania związków makrocyclicznych, takich jak szczypce molekularne, elementy struktur biologicznych oraz koniugatów flukonazolu [96,104]. Wydajne metody gwarantują efektywną syntezę związków steroidowych o aktywności biologicznej.

2.4.1. Koniugaty steroidowe o aktywności przeciwgrzybiczej i przeciwbakteryjnej

Flukonazol (**22**) jest związkiem z grupy triazoli, będący antybiotykiem oraz pełniący funkcję inhibitora syntezy ergosterolu (Rys. 12). Jego struktura opiera się na pierścieniu triazolowym związanym z fluorowanym benzenem oraz grupy hydroksylowej. Lekooporność grzybów obniżyła jego skuteczność, co spowodowało, że stał inspiracją w projektowaniu koniugatów steroidowo-triazolowych. Sprzężenie właściwości biologicznych związków steroidowych z aktywnością układów triazolowych daje pochodne o potencjalnym zastosowaniu jako leki przeciwgrzybicze o zwiększonej biobójczości i szerszym spektrum działania.

Rysunek 12. Flukonazol (**22**) i jego alkinowa (**23**) pochodna.

Pochodne odpowiednich kwasów żółciowych (deoksycholowego i cholowego) połączono pierścieniem 1,2,3-triazolowym ze zmodyfikowaną cząsteczką flukonazolu (**23**) (Rys. 13). Część steroidowa odgrywała rolę nośnika leku, a wbudowany triazol zwiększył funkcjonalność biologiczną uzyskanej molekuly. Grzyby z rodzaju *Candida*, takie jak *C. parapsilosis*, *C. albicans* i *C. Sporothrix* wykazywały prawie 100 % śmiertelność po zastosowaniu wobec nich nowych koniugatów (**24–27**), których aktywność przeciwgrzybicza oscylowała w zakresie MIC 3,12–6,25 mg/ml [96,105,106].

Rysunek 13. Koniugaty kwasów żółciowych i flukonazolu.

Wykorzystując metodę „click” sprzężono cząsteczkę mentolu z kwasami żółciowymi. Wybrane kwasy steroidowe poddano estryfikacji w obecności bromku propargilu i K_2CO_3 , a metylowany mentol przekształcono w azydek stosując NaN_3 w DMF. Następnie związki użyto jako reagenty w reakcji „click” (Schemat 21). Otrzymane pochodne 1,2,3-triazolu (**28–30**) charakteryzowały się lepszą aktywnością przeciwko szczepom *Enterococcus faecium* (MIC < 10 μM) niż mentol (MIC = 410 μM), kwasy żółciowe (MIC = 10, 20, 157, 410 μM) oraz antybiotyk cefiksym (MIC = 35410 μM) [107].

Schemat 21. Otrzymywanie koniugatów kwasów żółciowych i mentolu (28–30).

Związki o właściwościach farmakologicznych często zawierają grupy β -laktamowe. W strukturze penicyliny rozpoznano czteroczłonowe laktamy [108]. Rosnąca lekooporność bakterii i grzybów wymusiła zaprojektowanie hybryd opartych na związkach heterocyklicznych. Otrzymano koniugaty kwasów żółciowych połączone pierścieniem 1,2,3-triazolowym z cząsteczką pochodnej β -laktamu, które były skuteczne wobec szczepów grzybów: *C. albicans* (128 $\mu\text{g/ml}$), *Cryptococcus neoformans*, *Yarrowia lipolytica* (8 $\mu\text{g/ml}$), *Fusarium oxysporum*, *Benjaminiella poitrasii* (32 $\mu\text{g/ml}$) oraz bakteriom z rodzaju: *Escherichia coli* i *Staphylococcus aureus* (Rys. 14) [102].

Rysunek 14. Koniugat kwas żółciowy- β -laktam.

Koniugaty aminocholestanów połączone z pierścieniem imidazolowym lub pirydynowym (32–33) działały przeciwko kilku szczepom bakterii *S. aureus* (MIC < 4 $\mu\text{g/ml}$) (Rys. 15) [109].

Niezwykle skuteczne okazały się pochodne kwasu cholewskiego i lizyny. Związek (34) wykazywał aktywność wobec *S. aureus*, *E. Coli* i *C. albicans* (MIC < 8 $\mu\text{g/ml}$) oraz nie powodował degradacji erytrocytów ludzkich (Rys. 15). Natomiast inna pochodna tego

kwasu żółciowego była wysoce skuteczna przeciwko szczepom opornym *S. aureus* 1704, *E. Coli* 4052 i *C. auris* [110].

Rysunek 15. Koniugaty steroidowe o właściwościach antybakteryjnych i antygrzybiczych.

2.4.2. Koniugaty steroidowe o aktywności przeciw pasożytniczej

Pasożyty *Leishmania* to pierwotniaki z rodzaju *Leishmania*, przenoszone przez ukąszenia muchówek z rodziny *Phlebotominae*. Wywołują leishmaniozę, objawiającą się zmianami skórnymi, śluzówkowymi lub trzewnymi [111]. Z kolei malaria to choroba zakaźna wywołwana przez pasożyty z rodzaju *Plasmodium*, przenoszona na ludzi przez ukłucia samic komarów z rodzaju *Anopheles*. Objawia się gorączką, dreszczami, bólami mięśni i powikłaniami zagrażającymi życiu [112].

Biokoniugaty kwasu cholowego i 6-tiopuryny (**35–36**) otrzymane metodą „click” wykazywały w badaniach *in vivo* znacznie wyższą aktywność biologiczną niż chlorochina (lek stosowany w leczeniu malarii) oraz powodowały śmiertelność pasożyta *Leishmania* (Rys. 16). Testy pod kątem cytotoksyczności nie stwierdziły ich ingerencji w tkanki ssaka [113].

Rysunek 16. Koniugaty steroidowo-tiopurynowe o aktywności przeciwpasożytniczej.

Podobną skuteczność wobec leishmaniozy oraz prątka *Mycobacterium tuberculosis* określono dla związków triazolowych, zbudowanych z aminocholiny i kwasu żółciowego (Schemat 22). Koniugat (**38**) wykazywał właściwości przeciwgruźlicze przeciwko *M. tuberculosis* (MIC = 8,8 μ M) porównywalne ze stosowanymi lekami [114].

Schemat 22. Synteza koniugatów aminocholiny i kwasu cholowego.

2.4.3. Koniugaty steroidowe o aktywności przeciwnowotworowej

Projektowanie syntez związków o potencjalnym wykorzystaniu w terapiach przeciwnowotworowych ma fundamentalne znaczenie dla chemii organicznej. Z doniesień literaturowych wynika, że wzrastające zainteresowanie chemią steroidów zaowocowało opracowaniem efektywnych koniugatów o dużej aktywności wobec różnorodnych komórek raka [115]. Szczególną wartość mają te sprzężone z nukleozydami (Schemat 23) [116].

Schemat 23. Synteza steroidowo-urydynowych pochodnych triazolowych.

Agarwal i współpracownicy opisali pochodne kwasu żółciowego i aminokwasów zawierające układ 1,2,3-triazolowy (**41–48**) (Schemat 23, Rys. 17). Na podstawie testów *in vitro* potwierdzono ich aktywność przeciwko trzem liniom komórek nowotworowych (PC-3, MCF-7, IMR-32). Te same koniugaty wykazywały również działanie przeciwgruźlicze i były bezpieczne dla przeciętnej linii komórek ludzkiej nerki [117].

Rysunek 17. Biokonjugaty kwas żółciowy-nukleozyd zawierające pierścienie 1,2,3-triazolowe.

Natomiast koniugaty kwasu lithocholowego i aminokwasów opracowano, aby sprawdzić ich potencjał inhibujący sialilotransferazę. Enzym ten uczestniczy w kluczowym procesie biologicznym przetrwania komórek nowotworowych, zwanym hypersialilacją. Oceniono, że uzyskane w reakcji „click” pochodne steroidowe (**49–51**) hamują aktywność enzymu przy wartościach IC_{50} równym 6, 7 i 5 μM (Rys. 18) [98].

Rysunek 18. Pochodne kwasu lithocholowego (**49–51**) jako inhibitory sialilotransferazy.

Podobne hybrydy triazolowe oparte na szkielecie steroidowym również wykazywały aktywność antyproliferacyjną przeciwko liniom komórek K562 oraz HCT116 (Rys. 19). Biokoniugat, tzw. dU-nor-CDC (**52**) powodował apoptozę przy $IC_{50} = 42,9 \mu M$ (wobec K562), natomiast dU-UDC (**53**) był skuteczny przeciwko obu liniom komórek raka ($IC_{50} = 16,5$ i $22,0 \mu M$, odpowiednio dla K562 i HCT116) [118].

Rysunek 19. Biokoniugaty steroidowe powodujące apoptozę komórek raka.

Dane literaturowe donoszą również o biokoniugatach kwasu żółciowego i deoksyadenozyny łączony linkerem 1,2,3-triazolowym (Rys. 20). W wyniku kilkietapowej syntezy utworzone struktury (**54–56**) o właściwościach przeciwnowotworowych wobec

komórek raka białaczki K562 i Jurkat, o aktywności IC₅₀ odpowiednio $8,51 \pm 4,05 \mu\text{M}$ i $10,47 \pm 2,64 \mu\text{M}$ [119].

Rysunek 20. Hybrydy kwasów żółciowych i deoksyadenozyny.

Dendrymery, znane również jako „kieszenie molekularne”, wykazują niezwykle aktywność antyproliferacyjną. Udało się zaprojektować wydajną ścieżkę syntezy dendrymerów pierwszej generacji (chłodendrymerów), które następnie przekształcono w azydodendrymery drugiej generacji (Schemat 24). Jednocześnie cząsteczka kwasu żółciowego została efektywnie zmodyfikowana poprzez wprowadzenie grupy alkinowej. Testy MTT określiły, że pochodne steroidów zawierające pierścień triazolowy (**61–62**) skutkowały apoptozą komórek glejaka C6 przy IC₅₀ = 10,48 μM [120].

Schemat 24. Synteza dendrymerów (tzw. „kieszeni molekularnych”) o właściwościach antynowotworowych.

2.5. Znaczenie biologiczne syntezy koniugatów steroidowych i chemii „click”

Synteza nowych biokoniugatów steroidowych wskutek amplifikacji układów 1,2,3-triazolowych w cząsteczkę steroidu odgrywają kluczową rolę w rozwoju chemii związków naturalnych [121–125]. Chemia „click” umożliwia dostosowywanie właściwości związków steroidowych, co najczęściej prowadzi do powstania skuteczniejszych leków o minimalnych skutkach ubocznych. Dzięki koniugatom steroidowym można badać interakcje w układach biologicznych, wyjaśniając procesy fizjologiczne oraz mechanizmy chorób. Precyzyjny i selektywny charakter reakcji „click” promuje projektowanie cząsteczek o niezwykłym znaczeniu dla medycyny i biotechnologii. Sprzyja to tworzeniu efektywnych terapii, zaawansowanych biomateriałów i innowacyjnych technologii, korzystnych dla nauki i społeczeństwa.

Rysunek 21. Potencjał farmakoterapeutyczny opisanych w literaturze koniugatów steroidowych [P1].

Część eksperymentalna

Rozwój nowoczesnych terapii w farmakologii i chemii bioorganicznej bazuje na projektowaniu nowych związków o wielokierunkowym działaniu biologicznym. Biokoniugaty steroidowe o unikalnej aktywności biobójczej zyskały szczególne miejsce w opracowywaniu potencjalnych leków. Część eksperymentalna tej pracy opiera się na fundamentalnym zrozumieniu właściwości pochodnych steroidowych. Moje dotychczasowe badania w tym obszarze zaowocowały sześcioma publikacjami naukowymi, w których jestem pierwszą autorką, w tym w trzech z nich pełniłam również rolę autora korespondencyjnego.

Aby lepiej usytuować zakres badań własnych, w poniższym wprowadzeniu streszczono trzy kluczowe artykuły przeglądowe podsumowujące aktualne osiągnięcia naukowe dotyczące modyfikacji steroidów, ich potencjału terapeutycznego oraz możliwych zastosowań klinicznych. Podkreślają one znaczenie triazolowych modyfikacji kwasów żółciowych, koniugatów skwalaminy oraz zastosowania chemii „click” w tworzeniu nowych związków o działaniu przeciwnowotworowym, przeciwdrobnoustrojowym i neuroprotektoryjnym.

Biokoniugaty steroidowe stanowią obiecujące narzędzie w nowoczesnej chemii bioorganicznej i farmakologii. Oferują szerokie zastosowania terapeutyczne dzięki swojej unikalnej strukturze, wielokierunkowej aktywności biologicznej oraz niskiej toksyczności. Zawarte w pracach przeglądowych [P1], [P2] i [P4] badania podkreślają szczególne znaczenie modyfikacji chemicznych steroidów, takich jak skwalamina, kwasy żółciowe oraz koniugaty zawierające pierścienie 1,2,3-triazolowe, szczególnie w kontekście terapii przeciwnowotworowej, przeciwdrobnoustrojowej i przeciwpasożytniczej.

Biokoniugaty steroidowe wykazują wysoką skuteczność w zwalczaniu opornych szczepów bakterii i grzybów. Opisywane pochodne flukonazolu z kwasami żółciowymi, dzięki pierścieniowi 1,2,3-triazolowemu, zyskały większą stabilność i aktywność biologiczną wobec patogenów, takich jak *Candida albicans*. Podobne wyniki osiągnięto dla koniugatów steroidowych-triazolowych z mentolem, które przewyższyły skuteczność tradycyjnych antybiotyków.

Koniugaty steroidowe, takie jak związki kwasów żółciowych i nukleozydów, wykazały selektywną aktywność wobec komórek nowotworowych, m.in. raka piersi, prostaty czy neuroblastomy. Zastosowanie chemii „click” umożliwiło projektowanie makrocząsteczek o zwiększonej biodostępności i zdolności do celowanego działania przeciwnowotworowego.

Steroidowo-triazolowe pochodne kwasów żółciowych wykazały wyjątkową aktywność wobec *Mycobacterium tuberculosis* oraz pasożytów, takich jak *Leishmania*. Badania *in vivo* dowiodły, że niektóre koniugaty przewyższają działanie istniejących leków przeciwmalarycznych, takich jak chlorchicina, zachowując przy tym niską toksyczność lub będąc całkowicie bezpieczne dla komórek ludzkich.

Koniugaty steroidowe odgrywają istotną rolę w syntezie nośników leków oraz materiałów supramolekularnych, takich jak hydrogele czy dendrymery. Dzięki ich właściwościom amfipatycznym możliwe jest precyzyjne dostarczanie leków przeciwnowotworowych, diagnostycznych czy przeciwbakteryjnych.

W artykułach [P1] i [P4] omówiono różnorodne możliwości zastosowań biokoniugatów steroidowych w chemii supramolekularnej, farmakologii i medycynie. Szczególną uwagę poświęcono skwalaminie, naturalnemu steroidowi izolowanemu z wątroby rekina (*Squalus acanthias*). Skwalamina, będąca biokoniugatem spermidyny

i 7 α ,24-dihydroksy-5 α -cholestanu, wykazuje silne właściwości przeciwdrobnoustrojowe, przeciwwirusowe (w tym przeciw HIV) oraz przeciwnowotworowe. Badania wskazały na zdolność skwalaminy do hamowania angiogenezy, co spowalnia rozwój nowotworów płuc, piersi i jajników. W artykule podkreślono znaczenie modyfikacji chemicznych skwalaminy oraz jej pochodnych. Zastosowanie chemii „click” umożliwiło syntezę nowych koniugatów z pierścieniami triazolowymi, co zwiększyło ich stabilność oraz aktywność biologiczną. Opisano również koniugaty skwalaminy i kwasów żółciowych, które wykazały wysoką skuteczność wobec szczepów bakterii Gram-dodatnich i grzybów, takich jak *Candida albicans*. Ponadto, artykuł podkreśla rolę biokoniugatów steroidowych w syntezie nowych związków makrocyclicznych, takich jak organożele i receptory molekularne wykrywające biomarkery i kompleksujące cząsteczki gościa w układach biologicznych. Koniugaty kwasów żółciowych z flukonazolem wykazały prawie 100% skuteczność w zwalczaniu szczepów grzybów, takich jak *C. albicans* i *Sporothrix schenckii*. Doniesienia literaturowe wskazują na ogromny potencjał biokoniugatów steroidowych w opracowywaniu nowych leków celowanych, cząsteczek transportujących, jak również w terapii chorób przewlekłych i zakaźnych. Szczególny nacisk położono na możliwości precyzyjnego projektowania ich właściwości dzięki modyfikacjom chemicznym.

Artykuł przeglądowy [P2] podsumowuje szerokie zastosowanie biokoniugatów steroidowych w terapii chorób. Opisane związki naturalne, dzięki swojej unikalnej strukturze i właściwościom farmakologicznym, stanowią idealne nośniki bioaktywnych molekuł, takich jak aminokwasy, węglowodany czy peptydy. Połączenia te umożliwiają poprawę biodostępności, selektywności oraz ograniczenie toksyczności leków. Podkreślono szczególne znaczenie koniugatów steroidowych w terapii nowotworowej, zwłaszcza jako inhibitorów enzymów zaangażowanych w metabolizm steroidów (np. sulfotazy steroidowej) oraz jako środków wiążących receptory hormonalne. Koniugaty estradiolu z doksorubicyną wykazały zwiększoną skuteczność wobec komórek raka piersi zależnych od estrogeny. Ponadto glikozydy steroidowe, takie jak diosgenina, wykazały silne właściwości przeciwnowotworowe wobec komórek raka szyjki macicy. Kolejną istotną grupą są koniugaty steroidów z aminokwasami, które znajdują zastosowanie w terapii chorób neurodegeneracyjnych, takich jak choroba Alzheimera. Koniugaty sarsasapogeniny z aminokwasami wykazały potencjał neuroprotektoryjny poprzez hamowanie stresu oksydacyjnego i zwiększenie ekspresji neurotroficznych czynników wzrostu. Artykuł wskazuje także na potencjał steroidów w syntezie nowych hydrożeli i systemów dostarczania leków, co czyni je obiecującymi narzędziami w medycynie regeneracyjnej i nanotechnologii. Opisano m.in. steroidowe hydrożele do immobilizacji nanocząsteczek złota i srebra, co może mieć zastosowanie w terapii przeciwnowotworowej i diagnostyce.

Prace przeglądowe [P1], [P2] i [P4] podkreślają ogromny potencjał biokoniugatów steroidowych w rozwoju nowoczesnych leków. Ich wszechstronność, wynikająca z możliwości chemicznej modyfikacji, czyni je obiecującym narzędziem w walce z nowotworami, infekcjami i chorobami pasożytniczymi. Wyniki badań wskazują na konieczność dalszych prac nad ich właściwościami farmakologicznymi, aby w pełni wykorzystać ich potencjał terapeutyczny.

Opierając się na ogromnym spektrum doniesień literaturowych można postawić hipotezę, że sprzężenie szkieletu steroidowego kwasów żółciowych lub steroli z jednostką pierścienia 1,2,3-triazolową może prowadzić do otrzymania koniugatów o znacznym potencjale terapeutycznym.

Ze względu na dotychczasowy istotny wkład związków steroidowych w rozwój syntezy bioorganicznej cel pracy doktorskiej obejmował otrzymanie i charakterystykę:

- (1) 12 α -OAc i 7 α -OAc, 12 α -OAc 3 α -bromoacetoksy podstawionych pochodnych kwasu deoksycholowego i kwasu cholowego (**64–65**);
- (2) 12 α -OAc i 7 α -OAc, 12 α -OAc 3 α -azydoacetoksy podstawionych pochodnych kwasu deoksycholowego i kwasu cholowego (**67–68**);
- (3) 12 α -OAc i 7 α -OAc, 12 α -OAc 3 α -propargilowych podstawionych pochodnych kwasu deoksycholowego i kwasu cholowego (**78–79**);
- (4) 3 β -propargilowej pochodnej cholestanolu (**70**);
- (5) dimerów steroidowych kwasów żółciowych i steroli zawierających układ 1,2,3-triazolowy (**71–76**);
- (6) quasi-podandów kwasów żółciowych ze sztywną platformą pierścienia aromatycznego połączoną pierścieniami 1,2,3-triazolowymi (**82–85**);
- (7) koniugatów steroidowo-pirymidynowych połączonych linkerami 1,2,3-triazolowymi (**93–103**);

W ramach rozszerzonej charakterystyki otrzymanych związków:

- (8) przeprowadzono pełną analizę spektroskopową otrzymanych koniugatów steroidowych;
- (9) wykonano obliczenia semiempiryczne z wykorzystaniem metody PM5;
- (10) określono przewidywaną aktywność biologiczną *in silico* przy wykorzystaniu metody PASS;
- (11) określono potencjalne powinowactwa otrzymanych koniugatów do miejsc aktywnych wybranych domen białkowych w celu oceny ich aktywności przeciwbakteryjnej, przeciwgrzybiczej oraz przeciwnowotworowej.

Uzyskane wyniki dostarczyły istotnych informacji na temat innowacyjnych biokoniugatów steroidowo-triazolowych i ich możliwego zastosowania terapeutycznego.

1. Dimery kwasów żółciowych i steroli

Głównym założeniem współczesnej chemii bioorganicznej jest projektowanie i synteza nowych związków o potencjalnych zastosowaniach farmakoterapeutycznych. Szczególną uwagę przykuwa wykorzystanie chemii „click”, w tym reakcji cykloadycji Huisgena, do tworzenia biokoniugatów steroidowych. W ramach przeprowadzonych badań zsyntetyzowano innowacyjne koniugaty kwasów żółciowych (stanowiących „ogon”) i steroli (tzw. „głowa”), połączone za pomocą pierścienia 1,2,3-triazolu. Uzyskane związki zostały dokładnie scharakteryzowane metodami spektroskopowymi (NMR, FT-IR), spektrometrii mas (ESI-MS) oraz półempirycznymi i teoretycznymi obliczeniami chemicznymi, co pozwoliło ocenić ich potencjał terapeutyczny oraz stabilność fizykochemiczną [P8].

1.1. Synteza nowych biokoniugatów steroidowych

Dokonałam selektywnej syntezy bromoacetoksy podstawionych pochodnych kwasu lithocholowego (**63**) lub acylowanych pochodnych kwasów deoksycholowego (**64**) i cholowego

(65) (Schemat 25). Prezentowane badania stanowią pierwsze raporty dotyczące syntezy i charakterystyki spektroskopowej związków kwasów deoksycholowego i cholowego, które znajdują szerokie zastosowanie w syntezie organicznej. Pochodne te zostały utworzone w wyniku reakcji odpowiedniego estru metylowego (lub 12 α -OAc oraz 7 α -OAc, 12 α -OAc estru metylowego) z bromkiem kwasu bromooctowego w bezwodnym dichlorometanie.

(i) MeOH, *p*-TsOH; (ii) Ac₂O, Py, DMAP (dla 11&12); (iii) K₂CO₃, MeOH (dla 11&12); (iv) BrCH₂COBr, CH₂Cl₂(bezw)

Nr	R ¹	R ²	Wydajność [%]
63	H	H	98
64	H	OAc	92,7
65	OAc	OAc	70

Schemat 25. Synteza bromoacetoksy pochodnych kwasów żółciowych (63–65) [P8].

Warto podkreślić, że reaktywność grup hydroksylowych względem reakcji acetylowania, hydrolizy bądź redukcji wygląda następująco: 3 α -OH > 7 α -OH > 12 α -OH. Wynika to z ekwatorialnego położenia grupy 3 α -OH. W reakcjach tych wykazano jednocześnie, że stosowanie metanolu wobec czynnika zasadowego (K₂CO₃) prowadzi do selektywnej hydrolizy grup 3 α -OAc, 7 α -OAc, 12 α -OAc (o ile są obecne).

W celu otrzymania azydoacetoksy podstawionych pochodnych kwasów żółciowych (66–68) przeprowadziłam reakcję substytucji nukleofilowej (S_N2). Odpowiednie halogenoacetoksy podstawione pochodne steroidów (63–65) sprzężono z azydkiem sodu w obecności aprotycznego rozpuszczalnika (THF) i w podwyższonej temperaturze (50°C), uzyskując wysokie wydajności reakcji (do 95 %) (Schemat 26).

Nr	R ¹	R ²	Wydajność [%]

67	H	OAc	88,6
68	OAc	OAc	78

Schemat 26. Synteza azydoacetoksy pochodnych kwasów żółciowych (**66–68**) [P8].

W wyniku estryfikacji steroli z udziałem kwasu propargilowego i katalitycznej ilości *p*-TsOH otrzymano terminalne alkinyl cholesterolu i cholestanolu (**69–70**) (Schemat 27). Aktywacja tych steroidów zwiększyła ich elektrofilowość, co było niezbędne przed kluczową reakcją „click”.

Schemat 27. Synteza alkinowych pochodnych steroli (**69–70**) [P8].

Zaprojektowane warunki syntez otrzymywania bromoacetoksy pochodnych estrów metylowych pochodnych kwasów litocholowego, deoksycholowego oraz cholowego, jak również propargilowych pochodnych steroli opisano po raz pierwszy w pracy [P8]. Z analizy danych literaturowych wynika, że nie podjęto również wcześniej prób ich syntez, podobnie jak azydków steroidowych, dlatego dla związków (**64**), (**65**), (**67**), (**68**) i (**70**) przeprowadzono pełną charakterystykę spektroskopową.

3 α -azydoacetoksy pochodne kwasów żółciowych (**66–68**) oraz 3 β -propargilowe pochodne steroli (**69–70**) zastosowałam jako substraty w syntezie nowych biokonjugatów steroidowych połączonych pierścieniem 1,2,3-triazolowym. W warunkach reakcji specyficznych dla metody „click”, tj. przy użyciu pięciowodnego siarczany miedzi(II), askorbinianu sodu, w mieszaninie rozpuszczalników *tert*-butanol/woda (5:1) oraz w temperaturze nieprzekraczającej 65°C otrzymano z zadowalającą wydajnością

(51–80%) nieznane dotąd w literaturze chemicznej biokoniugaty kwasów żółciowych (71–76) ze sterolami o właściwościach proleków (Schemat 28).

Schemat 28. Synteza koniugatów kwasów żółciowych i steroli połączonych pierścieniem 1,2,3-triazolowym (71–76) [P8].

Wszystkie powyższe biokoniugaty zostały scharakteryzowane spektroskopowo (¹H NMR, ¹³C NMR, FT-IR) i spektrometrycznie (ESI-MS). Stałe przesiewowe dla atomów ¹³C i ¹H obliczono i przeanalizowano metodą GIAO/B3LYP/6–311G (d,p). Teoretyczne parametry porównano z uzyskanymi parametrami eksperymentalnymi otrzymując bardzo dobre rezultaty. W badaniach *in silico* wyznaczono aktywność farmakologiczną badanych związków oraz przeprowadzono dokowanie molekularne (domeny białkowe: 2Q85, 1KZN, 1EZF) [P8].

1.2. Analiza spektroskopowa

Na widmach ^1H NMR związków (**71–76**) zaobserwowano diagnostyczne przesunięcia chemiczne w postaci singletów w zakresie 8,24–8,20 ppm pochodzące od protonu obecnego w pierścieniach 1,2,3-triazolowych (Rys. 22). Z kolei sygnały wskazujące na położenie protonów grupy metylenowej $3\alpha\text{-OCO-CH}_2\text{-triazol}$ są obecne w zakresie 5,22–5,17 ppm. Widoczne przesunięcia chemiczne położone przy 5,04–4,86 ppm odpowiadają protonom przyłączonym w pozycjach $3'\alpha\text{-H}$ w szkielecie sterolu oraz $3\beta\text{-H}$ w szkielecie kwasów żółciowych. Sygnały pochodzące od protonów związanych z grupami acetylowymi $7\alpha\text{-OCOCH}_3$ oraz $12\alpha\text{-OCOCH}_3$ zaobserwowano jako singlety w zakresie 2,14–2,09 ppm dla wszystkich koniugatów. Natomiast przy 1,05–0,65 ppm zdiagnozowano charakterystyczne przesunięcia chemiczne odpowiadające protonom z grup metylowych $\text{CH}_3\text{-18/18'}$ (singlet), $\text{CH}_3\text{-19/19'}$ (singlet) i $\text{CH}_3\text{-21/21'}$ (dublet) połączonych z rdzeniem steroidowym, jak również $\text{CH}_3\text{-26'}$ i $\text{CH}_3\text{-27'}$ obecne w rozgałęzionym łańcuchu bocznym wyłącznie sterolu.

71

72

73

Rysunek 22. Fragmenty widm ^1H NMR związków (71–73) w zakresie diagnostycznych przesunięć chemicznych [P8].

Na podstawie interpretacji wykonanych widm ^{13}C NMR stwierdzono, że sygnały przesunięte w kierunku wyższych wartości ppm pochodzą od atomów węgla grup karbonylowych, obecnych zarówno w grupie estrowej przy atomach C-24 (174,73–174,47 ppm), jak i przy atomach $12\alpha\text{-OCO}$ (170,45–170,40 ppm) oraz przy atomach $7\alpha\text{-OCO}$

(170,28–170,22 ppm). Dla wszystkich biokoniugatów steroidowych w zakresie 128,83–128,74 ppm zaobserwowano sygnał związany z triazolowym atomem węgla. Sygnały w zakresie 77,48–75,15 ppm skorelowano z atomami węgla połączonymi z atomem tlenu przy C-3/3', C-7 i C-12 w szkielecie steroidowym. Z kolei przesunięcia atomów węgla z grup metylowych, tj. C-18/18', C-19/19', C-21/21', C-26' i C-27' szkieletu steroidowego zaobserwowano przy najniższych wartościach (22,94–12,02 ppm) (Rys. 23).

Rysunek 23. Fragment widma ¹³C NMR pochodnej kwasu litocholowego i cholesterolu (71) [P8].

Charakterystyczne pasma w widmach FT-IR wskazywały na obecność kluczowych grup funkcyjnych. W wyniku dokładnej analizy widm substratów i otrzymanych w reakcji „click” produktów, dla obu grup związków (tj. substratów i produktów) pasma w zakresie 1753–1738 cm⁻¹ odpowiadały drganiom atomów węgla grup karbonylowych. Jednocześnie na podstawie porównania tych widm oraz z uwagi na nieobecność charakterystycznych dla grup propargilowych i azydkowych pasm w zakresie 2111–2106 cm⁻¹ na analizowanych widmach koniugatów (71–76) zweryfikowano ich otrzymanie.

Przeprowadzona analiza spektrometryczna ESI-MS potwierdziła masy cząsteczkowe zsyntetyzowanych koniugatów kwasów żółciowych i steroli. Na podstawie widm masowych wszystkich nowych związków udowodniono obecność ich głównych jonów o większym powinowactwie do jonów sodu [M+Na]⁺, a o mniejszej intensywności związanej jonami potasu [M+K]⁺.

Oddziaływania między- i wewnątrzcząsteczkowe oraz konformacje cząsteczek zostały szczegółowo zbadane poprzez porównanie danych eksperymentalnych, uzyskanych w fazie skondensowanej, z wynikami obliczeń wykonanych dla fazy gazowej. W analizie porównano eksperymentalne przesunięcia chemiczne (¹H i ¹³C NMR) z wartościami obliczonymi dla wybranego biokoniugatu, wykorzystując metodę GIAO. Otrzymane korelacje były liniowe i opisane równaniem $\delta_{\text{exp}} = a + b\sigma_{\text{calc}}$, gdzie wartości parametrów wynosiły odpowiednio: dla ¹³C $a = 216,9071$ i $b = -1,848$, a dla ¹H $a = 30,6665$ i $b = -0,9303$. Wysokie współczynniki determinacji ($r^2 = 0,9942$ dla ¹³C NMR oraz $r^2 = 0,9905$ dla ¹H NMR) potwierdzają poprawność zoptymalizowanej geometrii cząsteczek (Rys. 24).

Rysunek 24. Eksperymentalne przesunięcia chemiczne (δ_{exp} , CDCl_3) w związku (73) w funkcji izotropowych stałych ekranowania magnetycznego (σ_{calc}) z obliczeń GIAO/B3LYP/6–311G(d,p); (a) protony i (b) atomy węgla-13 [P8].

1.3. Obliczenia semiempiryczne (PM5)

PM5 jest metodą półempiryczną stosowaną w chemii kwantowej, umożliwiającą szybkie i efektywne modelowanie struktur molekularnych oraz ich właściwości. Wykorzystuje uproszczone równania Schrödingera, uzupełnione o parametry empiryczne, dodane na podstawie wyników eksperymentalnych i dokładnych obliczeń *ab initio*.

Obliczenia metodą PM5 odegrały kluczową rolę w analizie właściwości fizykochemicznych i strukturalnych otrzymanych biokoniugatów kwasów żółciowych i steroli (Tabela 1). Zoptymalizowana geometria cząsteczek posłużyła do analiz dokowania molekularnego. Wartości ciepła tworzenia (HOF) niektórych struktur biokoniugatów, uzyskane w obliczeniach metodą PM5, są wynikiem kilku kluczowych czynników związanych z ich strukturą molekularną i właściwościami chemicznymi. W biokoniugatach zawierających pierścień 1,2,3-triazolowy oraz liczne podstawniki (np. grupy acetylowe) obserwuje się duże oddziaływania steryczne między fragmentami cząsteczki. Pierścień triazolowy odgrywa kluczową rolę w rozkładzie elektronów w cząsteczce. Jego zdolność do sprzężenia π – π z innymi elementami struktury może zarówno stabilizować, jak i destabilizować cząsteczkę, w zależności od rozmieszczenia grup funkcyjnych. Warto zauważyć, że wartość ciepła tworzenia HOF maleje wraz ze wzrostem grup estrowych, dlatego też za najbardziej stabilny energetycznie związek można uznać biokoniugaty kwasu cholowego (73) i (76). Porównując pochodne steroli należy uwzględnić wpływ obecnego wiązania podwójnego przy atomach węgla $\text{C}_5=\text{C}_6$ w cząsteczce cholesterolu, wskutek którego jego związki wykazywały minimalnie niższą trwałość (Rys. 25). Zastosowanie fragmentów sterolowych i kwasów żółciowych prowadzi do uzyskania struktur o mieszanym charakterze hydrofobowym i hydrofilowym. Tego typu właściwości mogą powodować lokalne napięcia w strukturze cząsteczki, wpływając na jej stabilność energetyczną. Wskazują również, które elementy strukturalne mogą być modyfikowane w przyszłych badaniach, aby uzyskać bardziej stabilne i potencjalnie bioaktywne związki.

Δ HOF₁ = HOF_{koniugaty_{syn}} (71–76) – HOF_{kwas_y żółciowe} (7–9). Δ HOF₂ = HOF_{koniugaty_{anti}} (71–76) – HOF_{kwas_y żółciowe} (10–12). Δ HOF₃ = HOF_{koniugaty_{syn}} (71–76) – HOF_{sterole} (1, 9). Δ HOF₄ = HOF_{koniugaty_{anti}} (71–76) – HOF_{sterole} (1, 9).

1.4. Aktywność biologiczna

Badania *in silico* metodą PASS

Synteza i izolacja nowych związków chemicznych, jak również modyfikacja struktury już znanych połączeń, wymagają oceny ich właściwości farmakologicznych oraz potencjalnego działania toksycznego. Tradycyjne badania *in vitro*, a następnie *in vivo*, są jednak czasochłonne i kosztowne. W związku z tym coraz większą rolę odgrywają analizy *in silico*, przeprowadzane z wykorzystaniem narzędzi takich jak program PASS.

Metoda ta pozwala nie tylko na skrócenie czasu poszukiwań biologicznie aktywnych związków, lecz także na wskazanie ich potencjalnych właściwości biologicznych. Dzięki temu możliwe jest szybsze wytypowanie prawdopodobnych związków do dalszych badań farmakologicznych. Program PASS, opierając się na strukturze cząsteczki, przewiduje zarówno jej potencjalne działanie farmakologiczne, jak i toksyczne. Mechanizm działania programu polega na porównaniu struktury badanego związku z danymi zawartymi w obszernej bazie, obejmującej około 1 000 000 biologicznie aktywnych związków i 5500 różnych aktywności biologicznych.

Program PASS znajduje szczególne zastosowanie przy analizie związków zawierających elementy substancji pochodzenia naturalnego lub metabolitów wtórnych. Narzędzie to oblicza prawdopodobieństwo wystąpienia danej aktywności biologicznej (PA) oraz jej braku (PI). Wysokie wartości PA (> 0,7) wskazują na duże prawdopodobieństwo potwierdzenia aktywności w badaniach eksperymentalnych. Dla wartości PA w przedziale 0,5–0,7 szansa ta jest mniejsza, a przy PA < 0,5 jest ona bardzo niska.

Warto również zauważyć, że obecność elementów znanych i aktywnych biologicznie w strukturze badanego związku zwiększa prawdopodobieństwo potwierdzenia aktywności biologicznej. Założenia te czynią program PASS niezwykle przydatnym narzędziem w procesie diagnozowania potencjalnych właściwości farmakologicznych.

Bazując na wynikach testów *in silico* uzyskanych dla otrzymanych koniugatów steroidowych można wnioskować o ich zróżnicowanych właściwościach biologicznych. Istnieje wysokie prawdopodobieństwo wykazywania przez cząsteczki działania przeciwbakteryjnego oraz przeciwgrzybicznego. Wiąże się to z interakcjami z lipidowymi strukturami błon komórkowych drobnoustrojów prowadzących do ich destabilizacji. Biokoniugaty wykazują przewidywane właściwości antagonistyczne wobec cholesterolu. W Tabeli 2 pokazano wybrane przewidywane aktywności biologiczne koniugatów (71–76).

Tabela 2. Przewidywana aktywność biologiczna wybranych koniugatów [P8].

PA > 0,70	71	72	73	74	75	76
Inhibitor gliceryloeteromonooksygenazy	–	0,71	0,75	0,72	0,75	0,79
Antagonista cholesterolu	0,84	0,76	0,76	0,71	–	–
Hipolipidemia	0,76	0,78	0,85	–	–	0,78
Antyhipercholesterolemia	0,73	–	0,75	–	–	–
Zapalenie trzustki	0,83	0,80	0,79	0,90	0,86	0,84

Aktywność przeciwbakteryjna

Badania dokowania molekularnego wykazały, że biokoniugaty mają zdolność do oddziaływania z białkami kluczowymi dla metabolizmu bakterii (Rys. 26). Szczególną uwagę zwrócono na zdolność do hamowania wzrostu bakterii Gram-dodatnich i Gram-ujemnych. Wśród analizowanych drobnoustrojów znalazły się:

- *Escherichia coli* – bakteria Gram-ujemna związana z zakażeniami dróg moczowych, przewodu pokarmowego i ran [126].
- *Staphylococcus aureus* – bakteria Gram-dodatnia odpowiedzialna za poważne zakażenia skórne, a także infekcje szpitalne [127].

Wyniki wskazują, że aktywność przeciwbakteryjna koniugatów jest ograniczona, jednak stwarzają perspektywę do dalszych modyfikacji chemicznych w celu zwiększenia ich skuteczności.

Rysunek 26. Interakcje ligandów i sposób wiązania dla związków (73) i (76) w 2Q85.

A, C – oznacza ligand (73) (zielony); B, D – oznacza ligand (76) (żółty) [P8].

Aktywność przeciwgrzybiczna

Wykazano wyraźnie większe działanie przeciwgrzybicze w porównaniu z działaniem przeciwbakteryjnym otrzymanych biokoniugatów steroidowych (71–76). Najsilniejszą aktywność przeciwgrzybiczą zaobserwowano wobec następujących szczepów grzybów:

- *Candida albicans* – grzyb odpowiedzialny za infekcje kandydozowe, szczególnie u osób z obniżoną odpornością [128].
- *Aspergillus niger* – pleśń mogąca wywoływać choroby płuc, w tym aspergilozę [129].
- *Cryptococcus neoformans* – drożdżak związany z ciężkimi zakażeniami ośrodkowego układu nerwowego u pacjentów z HIV/AIDS [130].

Koniugaty działają na kluczowe enzymy grzybów, co wskazuje na ich potencjał jako inhibitorów specyficznych szlaków metabolicznych.

Obecność pierścienia 1,2,3-triazolowego oraz właściwości amfifilowe związków mogą zakłócać funkcjonowanie błon komórkowych drobnoustrojów, prowadząc do ich uszkodzenia. Dokowanie molekularne sugeruje, że zsyntetyzowane koniugaty mogą wiązać się z enzymami odpowiedzialnymi za syntezę ściany komórkowej drobnoustrojów oraz za procesy metaboliczne, co prowadzi do ich dezaktywacji (Rys. 27).

Dzięki swojej chemicznej strukturze koniugaty są odporne na degradację enzymatyczną, co zwiększa ich trwałość w środowisku biologicznym i potencjalnie wydłuża czas działania. Ich potencjalne zastosowania obejmują terapie antygrzybicze szczególnie w zakażeniach wywołanych przez *Candida albicans* oraz możliwość wykorzystania ich jako składników preparatów przeciwdrobnoustrojowych o szerokim spektrum działania.

Rysunek 27. Interakcje ligandów i sposób wiązania dla związków (73) i (76) w 1EZF. A, C – oznacza ligand (73) (zielony); B, D – oznacza ligand (76) (żółty) [P8].

Zdolność koniugatów do wykazywania selektywnego działania przeciwko wybranym szczepom drobnoustrojów, szczególnie grzybów, czyni je obiecującymi kandydatami do dalszych badań. Ich stabilność chemiczna i specyficzne mechanizmy działania otwierają nowe możliwości terapeutyczne, zwłaszcza w kontekście rosnącej oporności drobnoustrojów na istniejące leki.

2. Quasi-podandry kwasów żółciowych

2.1. Synteza tripodstawionych pochodnych kwasów żółciowych

Zachęcona powyższym sukcesem przeprowadziłam reakcje syntezy quasi-podandów pochodnych kwasów żółciowych zawierających w strukturze pierścienie 1,2,3-triazolowe [P6]. Otrzymałam i przeanalizowałam właściwości fizykochemiczne propargilowej (77) oraz nowo opracowanych syntez 12 α -acetoksy- oraz 7 α ,12 α -diacetoksy propargilowych pochodnych kwasów żółciowych (78–79) (Schemat 29). Opierając się na założeniach chemii „click”, stanowiącej podstawową metodę nowoczesnej syntezy organicznej, zaprojektowałam reakcję otrzymywania wielkocząsteczkowych związków zawierających pierścienie 1,2,3-triazolowe (82–85). Tego typu układy cechuje stabilność w polarnych rozpuszczalnikach, wysoka odporność na procesy redukcji i utleniania oraz aktywność w tworzeniu wiązań wodorowych zwiększających ich trwałość.

(i) MeOH, *p*-TsOH; (ii) Ac₂O, Py, DMAP (dla **11&12**); (iii) K₂CO₃, MeOH (dla **11&12**);
 (iv) CH₃COOH, CH₂Cl₂(bezw.), *p*-TsOH

79	OAc	OAc	30

Schemat 29. Wprowadzenie grupy alkinowej w pozycję C-3 szkieletu steroidowego kwasów żółciowych [**P6**].

Schemat 30. Synteza 1,3,5-tris(azydometyleno)benzenu (**81**) [**P6**].

Serię quasi-podandów zsyntetyzowałam w reakcji estrów (lub acetylowanych estrów, nieznanymi jak dotąd w literaturze) propargilowych kwasów żółciowych z 1,3,5-tris(azydometyleno)benzenem w mieszaninie *tert*-BuOH/H₂O, z dodatkiem CuSO₄·5H₂O, askorbinianu sodu i w podwyższonej temperaturze (65°C). Na Rysunku 28 przedstawiono wszystkie tripodstawione koniugaty otrzymane z wysoką wydajnością. Ponadto, wyizolowano również dipodstawioną pochodną kwasu litocholowego (**82**) (Rys. 28). Monopodstawione pochodne kwasów żółciowych sprzężone z pierścieniem 1,2,3-triazolowym (z dwiema grupami azydkowymi N₃) nie powstają ze względu na ich niską trwałość. Otrzymanie dipodstawionych pochodnych występuje sporadycznie. Warto podkreślić, że opisaną dipodstawioną pochodną kwasu litocholowego (**82**) charakteryzuje wyższa wartość HOF w porównaniu z tripodstawioną pochodną tego kwasu (**83**), co świadczy o jej niestabilności (Tabela 3).

84	H	OAc	77
85	OAc	OAc	57

Rysunek 28. Quasi-podandy kwasów żółciowych zawierające układy 1,2,3-triazolowe [P6].

Zastosowanie reakcji 1,3-dipolarnej cykloaddycji (reakcji Huisgena) wykorzystującej katalityczne ilości miedzi(I) okazało się niezmiennie atrakcyjną i selektywną metodą syntezy pierścieni 1,2,3-triazolowych.

Zaprojektowane powyżej biokonjugaty (**82–85**) posiadają wbudowaną sztywną platformę pierścienia aromatycznego. Sprawia to, że ich cząsteczki będą sprawniej przyjmowały odpowiednią konformację. Płaski pierścień benzenowy może determinować wchodzenie w interakcje z powierzchnią biopolimerów, jak również stanowić swego rodzaju kotwicę w układach biologicznych.

Identyfikacja i scharakteryzowanie sześciu nowych związków (**78**, **79**) oraz (**82–85**) obejmowały wszechstronną analizę za pomocą technik spektralnych (¹H NMR, ¹³C NMR, FT-IR), spektrometrii mas (ESI-MS) i metody semiempirycznej PM5 [P6].

2.2. Analiza spektroskopowa

Charakterystyka spektroskopowa dostarczyła kluczowych informacji o strukturze związków, potwierdzając obecność pierścienia 1,2,3-triazolowego. Na widmach wszystkich koniugatów kwasów żółciowych zaobserwowano diagnostyczne przesunięcia chemiczne w zakresie 8,10–8,06 ppm odpowiadające protonom obecnym w pierścieniach 1,2,3-triazolowych. Ponadto w widmie ¹H NMR związku (**82**) widoczne jest istotne dla

identyfikacji przesunięcie chemiczne w postaci singletu przy 8,06 ppm, które można przypisać dwóm protonom pierścieni triazolowych, co świadczy o otrzymaniu dipodstawionej triazolowej pochodnej kwasu litocholowego. Co więcej, w widmach tego związku zaobserwowano również charakterystyczny sygnał przy 4,37 ppm, który można przypisać protonom z grupy $-\text{CH}_2-\text{N}_3$ (Rys. 29). Przesunięcia chemiczne w zakresie 5,09–4,81 ppm przypisano protonom $3\beta\text{-H}$, $7\beta\text{-H}$ i $12\beta\text{-H}$ w szkielecie steroidowym. Natomiast sygnały przy niższych wartościach (0,95–0,73 ppm) pochodziły od protonów z grup metylowych $\text{CH}_3\text{-21}$, $\text{CH}_3\text{-19}$ i $\text{CH}_3\text{-18}$.

Rysunek 29. Porównanie sygnałów zaobserwowanych na widmach ^1H NMR di- (**82**) i tripodstawionej (**83**) pochodnej kwasu litocholowego [**P6**].

Z kolei na wszystkich widmach ^{13}C NMR zidentyfikowano charakterystyczny sygnał z zakresie 129,5–123,8 ppm wskazujący na atom węgla z pierścienia 1,2,3-triazolowego. Przesunięcia odpowiadające atomom węgla z grup karbonylowych obecnych w cząsteczkach koniugatów zaobserwowano przy najwyższych wartościach (172,50–170,17 ppm). Niezmiennie, sygnały pochodzące od atomów węgla z grup metylowych, takich jak C-21, C-19 i C-21 połączonych bezpośrednio ze rdzeniem steroidowym kwasów żółciowych były widoczne przy w zakresie 23–10 ppm.

W widmach FT-IR zaobserwowano charakterystyczne pasma dla kluczowych grup funkcyjnych. Grupy karbonylowe ($\text{C}=\text{O}$) dawały intensywne pasma w zakresie

1745–1730 cm^{-1} , co potwierdza obecność estrów acetylowych. W przypadku propargilowych pochodnych kwasów żółciowych zaobserwowano pasma w zakresie 2120–2100 cm^{-1} , których nie odnotowano dla wykonanych widm FT-IR otrzymanych tripodstawionych triazolowych koniugatów steroidowych. W przypadku dipodstawionego koniugatu kwasu lithocholowego (**82**) dostrzeżono pasmo pochodzące od grupy azydkowej N_3 przy liczbie falowej 2099 cm^{-1} (Rys. 30).

Rysunek 30. Porównanie otrzymanych widm FT-IR związku (**82**) (z grupą N_3 , niebieski) oraz pozostałych związków (**83–85**) (czerwony) [P6].

Analiza wyników pozyskanych z otrzymanych widm spektrometrii masowej oraz wysoka zgodność danych eksperymentalnych z teoretycznymi dodatkowo potwierdzają poprawność struktur. Korelacja przesunięć chemicznych (^1H i ^{13}C) między wartościami eksperymentalnymi i obliczonymi (metodą GIAO) wykazała bardzo wysoką zgodność (^{13}C NMR: $r^2 = 0,9942$, ^1H NMR: $r^2 = 0,9905$). Jony molekularne o odpowiednich wartościach mas cząsteczkowych wskazują na utworzone zgodnie z oczekiwaniami struktury biokoniugatów. Fragmentacja masowa jonów molekularnych uzyskanych cząsteczek zweryfikowała obecność pierścieni 1,2,3-triazolowych bądź grup acetylowych.

Analiza spektroskopowa stanowi podstawę do dalszych badań nad właściwościami biologicznymi związków.

2.3. Obliczenia semiempiryczne (PM5)

Analiza wyników badań teoretycznych, opartych na obliczeniach metodą PM5, wskazuje, że monopodstawione pochodne kwasów żółciowych połączone pierścieniem 1,2,3-triazolowym (z dwiema wolnymi grupami N₃) nie powstają ze względu na bardzo wysokie wartości ciepła tworzenia. W przypadku kwasu lithocholowego zaobserwowano powstawanie dipodstawionych pochodnych, jednak ich stabilność była niska (Tabela 3). Wszystkie quasi-podandy wykazywały obecność interakcji π - π (typu „sandwich”) pomiędzy dwoma pierścieniami triazolowymi, przy czym obliczona separacja międzypłaszczyznowa wynosiła około 5,8 Å. Odległość ta jest większa o około 1,7 Å w porównaniu z klasycznymi interakcjami π - π , co wynika z faktu, że pierścień triazolowy jest bezpośrednio połączony ze sztywnym szkieletem aromatycznym, co wymusza zwiększoną odległość. Ponadto przestrzenne rozmieszczenie cząsteczek kwasów żółciowych i pierścieni 1,2,3-triazolowych może sprzyjać tworzeniu stabilnych kompleksów typu gospodarz-gość (Rys. 31).

Rysunek 31. Model molekularny koniugatu kwasu deoksycholowego z pierścieniami 1,2,3-triazolowymi (84) [P6].

Tabela 3. Ciepło tworzenia (HOF) [kcal/mol] otrzymanych pochodnych kwasów żółciowych [P6].

85	-1063,6189

2.4. Aktywność biologiczna

Przewidywana aktywność biologiczna (PASS)

Na podstawie badań *in silico* przewidziano potencjalną aktywność biologiczną zsyntetyzowanych związków. Ich potencjał farmakologiczny jest związany głównie z regulacją metabolizmu cholesterolu, dlatego mogą znaleźć zastosowanie jako antagoniści cholesterolu lub inhibitory enzymów metabolizmu lipidów [P6].

Dokowanie molekularne

Reduktaza HMG-CoA jest kluczowym enzymem odpowiedzialnym za syntezę cholesterolu w wątrobie. Badania nad nowymi inhibitorami reduktazy HMG-CoA mają istotne znaczenie dla zdrowia publicznego, ponieważ podwyższony poziom cholesterolu jest jednym z głównych czynników ryzyka chorób układu sercowo-naczyniowego, takich jak miażdżycy czy zawał serca. Jej hamowanie może skutecznie ograniczać produkcję cholesterolu, prowadząc do obniżenia jego stężenia we krwi [131, 132].

Zsyntetyzowane związki wykazują większe powinowactwo do domeny białka 1HW8 (PDB ID, reduktaza HMG-CoA) w porównaniu z mewastatyną, osiągając energię wiązania na poziomie -6,9 kcal/mol przy średniej energii -6,8 kcal/mol. Wyniki te wskazują, że nowe cząsteczki mogą potencjalnie pełnić rolę skutecznych inhibitorów reduktazy HMG-CoA (Rys. 32 i 33). Otrzymane związki, wykazujące większe powinowactwo do enzymu niż obecnie stosowana mewastatyna, mogą przyczynić się do opracowania bardziej efektywnych i bezpiecznych terapii obniżających poziom cholesterolu. Wprowadzenie takich innowacyjnych leków mogłoby nie tylko poprawić jakość życia pacjentów, ale także zredukować obciążenie systemu ochrony zdrowia związanego z leczeniem powikłań chorób sercowo-naczyniowych.

domeny białka 1HW8 [**P6**].

(średnia energia wiązania wynosi $-8,4$ kcal/mol) [P6].

3. Koniugaty steroidowo-pirymidynowe

3.1. Synteza koniugatów zawierających pierścienie 1,2,3-triazolowe

Unikatowa struktura i właściwości biologiczne steroidów determinują ich zastosowanie jako doskonałą platformę do modyfikacji chemicznych. Połączenie kwasów żółciowych lub steroli z zasadami pirymidynowymi, takimi jak uracyl i 2-tiouracyl umożliwia projektowanie biokoniugatów o potencjalnym działaniu wobec wirusów, bakterii, grzybów oraz komórek nowotworowych [133–136]. Zasady pirymidynowe jako kluczowy element strukturalny kwasów nukleinowych charakteryzuje zdolność do specyficznego oddziaływania z białkami enzymatycznymi i receptorami biologicznymi [137]. Włączenie cząsteczki uracylu bądź 2-tiouracylu do szkieletu steroidowego może istotnie poprawić ich farmakokinetykę oraz selektywność.

Przeprowadziłam syntezy modelowe z użyciem nowo opracowanych struktur *N*(1),*N*(3)-dipropargilowej pochodnej uracylu (**88**), *N*(1),*S*-dipropargilowej pochodnej 2-tiouracylu (**89**) i *N*(3),*S*-dipropargilowej pochodnej 2-tiouracylu (**90**) z 3 α -azydooctanami odpowiednich kwasów żółciowych (**66–68**) oraz 3 β -azydooctanami steroli (**91–92**) (Schemat 31 i 32). W wyniku reakcji „click” otrzymano 11 nowych 1,4-dipodstawionych 1,2,3-triazolowych koniugatów steroidowo-pirymidynowych (**93–103**) z wysokimi wydajnościami (Rys. 34). Zsyntetyzowane związki poddano szczegółowej analizie spektroskopowej (^1H NMR, ^{13}C NMR, FT-IR), spektrometrycznej (ESI-MS, EI-MS), wykonano obliczenia teoretyczne (PM5) oraz określono *in silico* ich potencjalną aktywność farmakologiczną (PASS, dokowanie molekularne) [P3].

Schemat 31. Synteza dipropargilowych pochodnych uracylu (**88**) i nowo opracowanych dipropargilowych pochodnych 2-tiouracylu (**89–90**) [P3].

Schemat 32. Synteza 3 β -azydooctanowych pochodnych steroli (**91–92**) [P3].

3.2. Analiza spektroskopowa

Analiza spektralna (¹H NMR, ¹³C NMR, FT-IR, EI-MS, ESI-MS) dostarczyła kompleksowych informacji o strukturze i stabilności nowych koniugatów steroidowo-pirymidynowych.

W widmie ¹H NMR dipropargilowych pochodnych 2-tiouracylu (89–90) charakterystyczne przesunięcia chemiczne dawały sygnał w postaci dubletów, które zaobserwowano przy 8,30 i 7,77 ppm i przypisano protonom CH-6 oraz przy 6,50 i 6,26 z CH-5 (Rys. 35). Sygnały odpowiadające protonom przy atomie węgla w wiązaniu CH₂–N(1) pojawiają się jako podwójne singlety przy 5,03 i 4,85 ppm, podobnie jak przesunięcia chemiczne pochodzące od protonów obecnych w grupie metylenowej CH₂–S przy 4,02 i 3,91 ppm. W zakresie 2,53–2,19 ppm zidentyfikowano charakterystyczne sygnały w postaci tripletów pochodzące od protonów przy wiązaniu C≡CH.

89

90

Rysunek 35. Fragmenty widm ¹H NMR alkinowych pochodnych 2-tiouracylu (**89**, **90**) [P3].

Diagnostyczne przesunięcia chemiczne pochodzące od protonów z pierścieni 1,2,3-triazolowych zaobserwowano dla wszystkich koniugatów (**93–103**) jako singlety w zakresie 7,90–7,70 ppm (Rysunek 36). Charakterystyczne sygnały w postaci dubletów odpowiadające protonom przy atomach węgla CH-6 i CH-5 zaobserwowano przy 8,26–8,25 i 6,45 ppm (dla związków **101–103**), 7,77–7,75 i 6,22–6,20 ppm (dla związków **98–100**),

7,46–7,45 i 5,75–5,74 ppm (dla związków **93–97**). Protony obecne w grupach metylenowych N-CH₂-triazol i S-CH₂-triazol można zinterpretować jako singlety położone odpowiednio przy 5,54–5,52 (N(3)), 5,34–5,33 (N(1)) i 4,56–4,50 ppm. Przesunięcia chemiczne pochodzące od protonów z grup metylenowych CH₂ łączących szkielet steroidu z pierścieniem triazolowym są położone w widmach ¹H NMR koniugatów steroid-uracyl (**93–97**) w zakresach 5,25–5,23 i 5,13–5,11 ppm. W przypadku związków (**98–103**) podobne sygnały w postaci singletów zaobserwowano przy 5,15–5,08 ppm. Na widmach ¹H NMR wszystkich związków (**93–103**) występują charakterystyczne przesunięcia chemiczne w zakresie 4,86–4,61 ppm należące do protonów przy 3'α-H i 3'β-H. Dla pochodnej cholesterolu (**96**) diagnostyczny jest szeroki singlet odpowiadający protonowi 6'-H przy 5,38 ppm.

95

99

Rysunek 36. Diagnostyczne sygnały widma ¹H NMR zidentyfikowane dla triazolowych związków kwasu cholowy-uracyl (**95**) i kwas deoksycholowy-tiouracyl (**99**) [P3].

Interpretacja widm ^{13}C NMR związków (**89**) i (**90**) wskazuje na sygnały pochodzące od atomów węgla C(4)=O, C(2)-S, C-6, C-5 odpowiednio przy 169,8–160,7, 167,5–160,7, 157,8–151,9 i 110,8–104,1 ppm. Sygnały od atomów C $\equiv$ C obserwowano w zakresie 79,7–70,5 ppm, natomiast sygnały odpowiadające atomom węgla z grup metylenowych CH₂ obserwowano w zakresie 54,1–19,4 ppm.

Na widmach ^{13}C NMR wszystkich koniugatów (**93–103**) sygnały diagnostyczne odpowiadające atomom węgla z pierścienia triazolowego, takie jak C=CH, dają sygnały odpowiednio przy 145,7–138,8 i 125,4–123,3 ppm. Z drugiej strony, atom węgla z połączenia metylenowego steroid-CH₂-pierścienia triazolowy zaobserwowano przy 51,2–51,0 ppm.

Na widmach FT-IR występują charakterystyczne dla grup karbonylowych pasma drgań rozciągających przy maksimum absorpcji w zakresie 1745–1730 cm⁻¹. Pasma absorpcji związane z wiązaniami N-H w cząsteczce uracylu i 2-tiouracylu są obecne w zakresie 3220–3120 cm⁻¹, co potwierdza udział pierścienia pirymidynowego w strukturze biokoniugatów.

Analiza widm EI-MS dostarczyła informacji o przyłączeniu grup propargilowych do odpowiednich atomów azotu (N(1) lub N(3)) i siarki w otrzymanych pochodnych 2-tiouracylu (**89–90**) (Schemat 33). Z kolei po interpretacji widm ESI-MS utworzonych biokoniugatów (**93–103**) zweryfikowano ich masy cząsteczkowe. Zaproponowana fragmentacja masowa struktur potwierdziła stabilność układów 1,2,3-triazolowych.

Pierścień pirymidynowy w związku (**89**) ulega otwarciu w wyniku pierwotnej fragmentacji typu α , prowadząc do powstania dwóch alternatywnych ścieżek fragmentacyjnych skutkujących powstaniem różnych jonów analitycznych. W jednej z dróg fragmentacji, dalszy rozpad typu α , a następnie reakcja typu retro-Dielsa-Aldera, prowadzi do powstania jonu nieparzysto elektronowego obserwowanego przy $m/z = 107$. W drugiej ścieżce, w wyniku indukowanego rozpadu α , generowany jest jon parzysto elektronowy o $m/z = 97$.

W przypadku związku (**90**), będącego pochodną typu N(3)S, obserwuje się dwa możliwe przebiegi fragmentacji typu α , obejmujące eliminację rodnika C₃H₃^{*} z atomu azotu z ugrupowania N(3), bądź atomu siarki. W obu przypadkach prowadzi to do powstania jonów parzysto elektronowych o $m/z = 165$.

Schemat 33. Możliwe fragmentacje związków (89) i (90) podczas analizy EI-MS [P3].

3.3. Obliczenia semiempiryczne (PM5)

Obliczone wartości ciepła tworzenia dla koniugatów wskazują na stabilność energetyczną hybryd steroidowo-uracylowych (93–97) (Tabela 4). Najwyższą trwałością charakteryzują się związki kwasu cholowego (95, 100, 103), co może być związane z obecnością grup 7 α -OAc, 12 α -OAc oraz wiązaniem estrowym w łańcuchu bocznym (Rys. 37). Obecność atomu siarki w pochodnych 2-tiouracylu spowodowały wyższe wartości HOF ze względu na steryczne oddziaływania w cząsteczce oraz większą polaryzowalność. Obliczenia wskazały na obecność silnych wewnątrzcząsteczkowych wiązań wodorowych między grupami karbonyłowymi a pirymidynowymi, które stabilizują utworzone struktury. Obecność pierścienia 1,2,3-triazolowego sprzyja trwałości układu dzięki interakcjom π - π i zwiększeniu sztywności strukturalnej.

Tabela 4. Ciepła tworzenia uzyskane dla pochodnych pirymidyn (**88–90**) i dla koniugatów steroidowych (**93–103**) [P3].

Nr	Ciepło tworzenia HOF [kcal/mol]
88	28,9829
89	97,0622
90	90,6298
93	–439,5148
94	–606,8373
95	–784,1348
96	–272,6631
97	–321,9369
98	–370,6792
99	–546,0568

Rysunek 37. Modele molekularne koniugatu cholesterolu z uracylem (**96**) i kwasu deoksycholowego z 2-tiouracylem (**102**) [P3].

3.4. Aktywność biologiczna

Otrzymane hybrydy steroidowo-pirymidynowe połączone pierścieniem 1,2,3-triazolowym wykazują szerokie spektrum potencjalnych właściwości biologicznych, co zostało potwierdzone za pomocą metod predykcyjnych (PASS) oraz dokowania molekularnego.

Na podstawie badań *in silico* przewidziano, że wybrane biokoniugaty steroidowe wykazały potencjalną aktywność przeciw bakteriom Gram dodatnim (*Staphylococcus aureus*) i Gram ujemnym (*Escherichia coli*), jak również grzybom z rodzaju *Candida albicans*. Ich działanie przeciwdrobnoustrojowe jest związane z oddziaływaniem z enzymami kluczowymi w metabolizmie wymienionych patogenów, takimi jak syntaza skwalenu (1EZF) i giraza-DNA (1KZN) (Rys. 38 i 39). Białko 1EZF bierze udział w biosyntezie ergosterolu, niezbędnego składnika błony komórkowej u grzybów, a 1KZN jest istotna dla prawidłowej replikacji DNA w komórkach bakterii. Wyższa energia powinowactwa koniugatów niż ligandy natywne wskazują na ich potencjał proleków (Tabela 5).

Tabela 5. Otrzymane wartości energii powinowactwa [kcal/mol] koniugatów do określonych domen białkowych [P3].

Domena białka ID	Nazwa ligandu				
	1EZF	1KZN	2H94	2Q85	5V5Z
Natywny	-11.9	-9.1	-14.6	-10.9	-10.5
89	-5.7	-5.7	-6.2	-5.9	-5.9
90	-6.2	-5.2	-5.6	-5.7	-5.6
93	-11.4	-7.1	-9.5	-11.3	-11.3

100	-10.2	-8.0	-9.3	-11.6	-9.7
101	-11.3	-8.8	-10.2	-11.2	-11.9
102	-10.9	-7.6	-10.2	-9.5	-10.8
103	-10.4	-8.2	-9.3	-10.1	-10.1

**Rysunek 38.** Wiązania wodorowe utworzone pomiędzy koniugatem (97) a miejscem aktywnym syntazy skwalenu (1EZF) określające potencjalną aktywność przeciwgrzybiczną [P3].

Rysunek 39. Wiązania wodorowe utworzone między ligandem pochodnej cholesterolu (96) a domeną białkową bakterii (1KZN) określającą potencjalną aktywność przeciwbakteryjną [P3].

Testy *in silico* metodą PASS prognozują zdolność pochodnych 1,2,3-triazolowych do ochrony komórek przed stresem oksydacyjnym (Tabela 6). Przewidywana aktywność cytoprotekcyjna wiąże się z amfipatycznością kwasów żółciowych i steroli. Wyniki pokazują, że otrzymane struktury zostały zidentyfikowane jako potencjalne inhibitory enzymów (monooksygenazy gliceryloeterowej i alkiloacetyloglicerofosfatazy) związanych z reakcjami zapalnymi skóry. Ponadto, związki te posiadają charakter antycholestatyczny, co może mieć znaczenie w leczeniu zaburzeń przewodu żółciowego.

Tabela 6. Przewidywana aktywność biologiczna wybranych koniugatów steroidowo-pyrimidynowych [P3].

Aktywność biologiczna 50 <	Koniugat				
	93	96	97	98	102
Inhibitor monooksygenazy gliceryloeterowej	71	61	73	69	69
Inhibitor alkiloacetyloglicerofosfatazy	68	–	71	–	52
Choroby skóry	69	64	67	59	–
Cytoprotekcyjna	61	–	–	57	60
Zaburzenia metabolizmu żółci	56	–	61	–	–
Dermatologiczna	57	59	57	52	54
Niepłodność u kobiet	53	58	57	–	–
Choroby związane z prostatą	53	58	53	–	–
Antygrzybiczna	52	58	54	50	50
Antyalergiczna	52	54	54	–	–
Inhibitor CYP17	–	65	–	–	–
Inhibitor reduktazy DELTA14-sterolowej	–	60	–	–	–

Przeprowadzone dokowanie molekularne określiło działanie przeciwnowotworowe biokoniugatów steroidowo-pirymidynowych (Tabela 7, Rys. 40). Wykazując wyższą energię powinowactwa do białka związanego z regulacją ekspresji genów i cyklu komórkowego (LSD1, demetylaza-1 specyficzna dla lizyny) niż powinowactwo ligandu natywnego predysponują do hamowania wzrostu komórek nowotworowych poprzez mechanizmy epigenetyczne.

Rysunek 40. Potencjalne wiązania wodorowe między ligandem (**98**) a miejscem aktywnym białka związanego z proliferacją komórek nowotworowych (2H94) [P3].

Dzięki wysokiej specyficzności względem enzymów docelowych mogą one znaleźć zastosowanie w terapiach nowotworowych, leczeniu infekcji oraz jako związki wspomagające ochronę komórek przed uszkodzeniami.

Podsumowanie

Artykuły przeglądowe dostarczyły szczegółowego wglądu na aktualny stan wiedzy dotyczący syntezy biokoniugatów steroidowych i ich właściwości biologicznych. Poruszana tematyka skupiała się na skwalaminie jako fundamentalnym związku promującym projektowanie nowych pochodnych steroidowych o zastosowaniu w terapiach przeciwnowotworowych, przeciwwirusowych i przeciwdrobnoustrojowych. Zwrócono również uwagę na ich zdolność do hamowania angiogenezy i agregacji białek w chorobach neurodegeneracyjnych.

Silną aktywnością biobójczą wyróżniają się koniugaty oparte na szkielecie steroidowym kwasów żółciowych z wbudowanymi pierścieniami 1,2,3-triazolowymi, potęgującymi ich zastosowanie w układach biologicznych. Modyfikacje rdzenia steroidowego z wykorzystaniem reakcji chemii „click” prowadzą do otrzymywania potencjalnych leków [P1, P2, P4].

Wyniki uzyskane w badaniach własnych wniosły istotny wkład w rozwój wiedzy o nowych biokoniugatów steroidowych, szczególnie w zakresie ich syntezy, charakterystyki spektroskopowej i przewidywanych właściwości farmakologicznych.

Opracowano efektywne warunki syntezy jedenastu nowych pochodnych kwasów żółciowych i steroli, w tym sześciu biokoniugatów połączonych pierścieniami 1,2,3-triazolowymi, które scharakteryzowano spektroskopowo. Związki te wyróżnia stabilność chemiczna, co dowiodły obliczenia teoretyczne. Wykazano, że nowe koniugaty wykazują potencjalną aktywność biologiczną w kierunku działania przeciwgrzybicznego i przeciwbakteryjnego [P8].

Zsyntetyzowano dwie propargilowe acetylowe pochodne kwasów żółciowych oraz cztery struktury quasi-podandów kwasów żółciowych zawierających pierścienie 1,2,3-triazolowe. Takie układy mogą tworzyć kompleksy supramolekularne. Analiza spektroskopowa i wyniki obliczeń semiempirycznych metodą PM5 potwierdziły poprawność otrzymanych struktur i trwałość wszystkich cząsteczek. Koniugaty wyróżnia potencjał antyhipercholesterolemiczny [P6].

Z kolei trzynaście nowych hybryd steroidowo-pirymidynowych charakteryzuje zdolność do oddziaływań z enzymami uczestniczącymi w metabolizmie lipidów i w procesach przeciwnowotworowych. Analizy dokowania molekularnego wskazały na ich potencjalną aktywność antyproliferacyjną oraz na zastosowanie tych związków w terapii przeciwko grzybom i bakteriom [P3].

Zaprojektowane struktury trzydziestu nowych pochodnych kwasów żółciowych i steroli wniosły nowe perspektywy wiedzy w dziedzinie chemii bioorganicznej. Opracowane koniugaty zawierające pierścienie 1,2,3-triazolowe wykazują wysoką przewidywaną aktywność farmakologiczną, szczególnie przeciwnowotworową, przeciwdrobnoustrojową i cytoprotekcyjną. Prezentowane wyniki stanowią punkt wyjścia dla dalszych badań nad zastosowaniem uzyskanych koniugatów steroidowo-triazolowych w medycynie, farmakologii lub jako nośniki substancji bioaktywnych.

Tabela 7. Wykaz numeracji związków w artykułach naukowych (**Nr_A**) w porównaniu z obowiązującymi w pracy (**Nr_P**).

Streszczenie

Synteza, analiza spektroskopowa oraz badania biologiczne *in silico* nowych koniugatów steroidowych zawierających układy triazolowe

mgr inż. Anna Kawka

Promotor: prof. UAM dr hab. Tomasz Pospieszny

Promotor pomocnicza: dr inż. Hanna Koenig

Praca doktorska koncentruje się na projektowaniu, syntezie, izolacji i oczyszczeniu oraz charakterystyce spektroskopowej i przewidywaniu aktywności biologicznej nowych biokoniugatów steroidowych. Opracowane związki stanowią połączenie fragmentów kwasów żółciowych oraz zasad pirymidynowych za pomocą pierścieni 1,2,3-triazolowych, uzyskanych w wyniku reakcji typu „click”, w kontekście poszukiwania nowych związków o potencjale farmakologicznym. Rozprawa obejmuje zarówno przegląd literaturowy, jak i oryginalne badania eksperymentalne i teoretyczne.

W części literaturowej omówiono znaczenie biokoniugatów steroidowych, takich jak skwalamina i jej pochodne, w terapiach farmakologicznych. Zwrócono szczególną uwagę na zastosowanie chemii „click” w modyfikacji kwasów żółciowych i steroli. Takie podejście umożliwia tworzenie stabilnych i bioaktywnych struktur supramolekularnych. Skrupulatnie przeanalizowano współczesne osiągnięcia w zakresie koniugatów steroidowo-triazolowych jako inhibitorów enzymów i potencjalnych leków przeciwinfekcyjnych.

W części badawczej opracowano trzy grupy nowych związków: (1) koniugaty kwasów żółciowych i steroli z pierścieniami 1,2,3-triazolowymi wykazującą przewidywaną aktywność przeciwrzybiczną i przeciwbakteryjną; (2) quasi-podandy z układami triazolowymi strukturalnie przypominają układy supramolekularne podatne na tworzenie kompleksów typu gospodarz-gość, co otwiera możliwości w nanotechnologii i systemach dostarczania leków, zwłaszcza w leczeniu hipercholesterolemii; (3) hybrydy steroidowo-pirymidynowe (z uracylem i 2-tiouracylem) charakteryzuje zdolność do interakcji z enzymami metabolizmu lipidów i potencjalne zastosowanie w terapiach przeciwnowotworowych, przeciwdrobnoustrojowych i dermatologicznych.

Wyniki analiz spektroskopowych (^1H i ^{13}C NMR, FT-IR) i spektrometrycznych (ESI-MS, EI-MS) oraz obliczeń teoretycznych (PM5, GIAO) potwierdziły poprawność struktur molekularnych i stabilność chemiczną związków. Badania *in silico* metodą PASS oraz dokowania molekularnego wykazały ich szerokie spektrum potencjalnej aktywności biologicznej, obejmujące działanie przeciwnowotworowe, przeciwdrobnoustrojowe, cytoprotekcyjne i przeciwzapalne.

Praca przyczynia się do rozwoju chemii bioorganicznej, oferując nowe perspektywy w projektowaniu związków terapeutycznych o wielokierunkowym działaniu biologicznym.

Abstract

Synthesis, spectroscopic analysis and *in silico* biological studies of new steroid conjugates containing triazole systems

mgr inż. Anna Kawka

Supervisor: prof. UAM dr hab. Tomasz Pospieszny

Assistant supervisor: dr inż. Hanna Koenig

The doctoral thesis focuses on the design, synthesis, isolation, purification, spectroscopic characterisation and prediction of biological activity of new steroid bioconjugates. The developed compounds constitute a combination of fragments of bile acids and pyrimidine bases using 1,2,3-triazole rings obtained by a „click” reaction in the context of searching for new compounds with pharmacological potential. The dissertation includes both a literature review and original experimental and theoretical studies.

The literature section discusses the importance of steroid bioconjugates in pharmacological therapies, such as squalamine and its derivatives. Special attention was paid to the use of „click” chemistry in the modification of bile acids and sterols. This approach allows the creation of stable and bioactive supramolecular structures. The contemporary achievements in steroid-triazole conjugates as enzyme inhibitors and potential anti-infective drugs were meticulously analysed.

In the research part, three groups of new compounds were developed: (1) bile acid and sterol conjugates with 1,2,3-triazole rings exhibit predicted antifungal and antibacterial activity; (2) quasi-podands with triazole systems structurally resemble supramolecular systems susceptible to forming host-guest complexes, which opens up opportunities in nanotechnology and drug delivery systems, especially in treating hypercholesterolemia; (3) steroid-pyrimidine hybrids (with uracil and 2-thiouracil) are characterized by the ability to interact with lipid metabolism enzymes and potential use in anticancer, antimicrobial and dermatological therapies.

The results of spectroscopy analyses (^1H and ^{13}C NMR, FT-IR), spectrometry analyses (ESI-MS, EI-MS) and theoretical calculations (PM5, GIAO) confirmed the correctness of the molecular structures and chemical stability. *In silico* studies using PASS and molecular docking methods have shown their broad spectrum of potential biological activity, including anticancer, antimicrobial, cytoprotective and anti-inflammatory effects.

The work contributes to the development of bioorganic chemistry, offering new perspectives in designing therapeutic compounds with multidirectional biological activity.

TRIAZOLE-BASED MODIFICATIONS OF BILE ACIDS: PROMISING STRATEGIES FOR COMBATING INFECTIONS AND CANCER – A REVIEW

Anna Kawka, Hanna Koenig, Tomasz Pospieszny
Department of Bioactive Products, Faculty of Chemistry,
Adam Mickiewicz University, Poznań
email: anna.kawka@amu.edu.pl

Abstract: The specific structure and high biological activity of bile acids resulted in their use in the design of new compounds with negligible toxicity and significant pharmacological activity. Natural steroid conjugates occupy a special place among natural products due to their participation in most metabolic pathways. Literature data indicate that in recent years, there has been a significant increase in interest in isolating, synthesizing, and modifying new steroid conjugates with broad physical, biological, and pharmacotherapeutic properties. Bile acid derivatives containing the 1,2,3-triazole ring are fundamental in drug discovery. Previous studies of steroid-triazole conjugates confirm their essential importance as compounds with high biocidal, antibacterial, and anticancer properties.

Keywords: bile acids, 1,2,3-triazole ring, anticancer and antimicrobial activity

1. Introduction

Compounds of natural origin play an essential role in the search for new molecules with biocidal properties. Their high availability and unique structure have made them used in the design of new drug syntheses [1, 2]. Bile acids are formed as products of cholesterol (**1**) metabolism (fig. 1). Their glycine/taurine-conjugated salts are stored in the gallbladder. Bile acids (e.g., lithocholic acid, deoxycholic acid, cholic acid) are responsible for the digestion of lipids in the small intestine. As surfactants, they help to lower surface tension and emulsify fats. Moreover, they regulate glucose homeostasis, cholesterol, fat transport, and enterohepatic circulation [3–6].

Fig. 1. Shortened scheme of the biosynthesis of bile acids from cholesterol (2–5)

Bile acids (2–5) have a chiral rigid skeleton, a long side chain with a carboxyl group, and hydroxyl groups (3 α -OH, 7 α -OH, 12 α -OH) with different reactivity and amphiphilic properties. Their low cost and several physicochemical properties make them ideal building materials in drug design. Most importantly, this use of bile acids entirely minimizes the risk of unwanted side effects [7–9]. Successful attempts to modify steroid molecules have often been carried out through coupling chemistry. The obtained steroid-triazole conjugates were distinguished by low toxicity, susceptibility to multidrug resistance, and bioavailability. They have become leading compounds in designing new biomolecules with biocidal and especially anticancer activity [10–14].

1,2,3-triazole systems are five-membered heterocyclic compounds of crystalline nature. They are soluble in water and alcohol. They resist oxidative/reductive stress, hydrolysis, and metabolic degradation. Triazole derivatives can also bind to receptors (or enzymes) through interactions, such as hydrogen bonding, van der Waal's forces, or hydrophobic interactions [15, 16]. It is worth noting that bonds formed in this way are resistant to cleavage by, for example, proteases. As a result, triazole systems can be analogues of the peptide bond [17]. Literature data show that 1,2,3-triazole compounds are characterized by exceptional pharmacotherapeutic activity, especially antihypertensive, antimalarial, antidiabetic, anticonvulsant, antioxidant, antidepressant, antiplasmodic, antimicrobial, antibacterial, anti-inflammatory, and antituberculosis [18–34].

Usually, 1,2,3-triazole derivatives are obtained by thermal 1,3-dipolar cycloaddition of azides and alkynes using a catalytic amount of copper(I) ions (fig. 2). The “Huisgen reaction” synthesizes macromolecular steroid-triazole conjugates [35–37]. The specific structure, amphipathic nature, and high activity of functional groups of bile acids determine their crucial importance in bioorganic synthesis. Steroid acids have become a precursor to preparing macrocyclic compounds or fluconazole derivatives, which have potent pharmacotherapeutic activity [38, 39].

Fig. 2. Scheme of the preparation of 1,4- or 1,5-disubstituted 1,2,3-triazole rings

2. Steroid-triazole conjugates with biological activity

2.1. Bioconjugates with antibacterial and antifungal properties

Fluconazole is a potent compound used as an antibiotic in antifungal and antibacterial therapy (fig. 3). The growing resistance of bacteria to this drug made it necessary to change its structure.

Fig. 3. Fluconazole (**6**) and its alkyne derivative (**7**)

A molecule of a suitable bile acid linked to fluconazole via a 1,2,3-triazole ring was designed (fig. 4). In this way, the amphipathic nature of bile acids was used as a drug transporter inhibiting bacterial strains' growth. On the other hand, thanks to the presence of the triazole ring, the new biomolecule gained resistance to enzymatic degradation. Compounds obtained (**8–11**) were almost entirely effective against strains of *Candida parapsilosis*, *Candida albicans*, and *Sporothrix schenckii* (MIC = 3.12–6.25 mg/ml) [39–41].

Fig. 4. Conjugates of fluconazole and bile acids (**8–11**) with antifungal activity

A similar “click” reaction was performed for the menthol molecule (fig. 5). The corresponding bile acids were esterified with propargyl bromide in the presence of K_2CO_3 . On the other hand, in the reaction of methylated menthol with NaN_3 in DMF, a compound was obtained, which, by coupling with a bile acid derivative, gave triazole. The obtained 1,2,3-triazole derivatives (**12–14**) showed higher antimicrobial activity ($MIC < 10 \mu M$) against strains *Enterococcus faecium* menthol ($MIC = 410 \mu M$) and bile acids ($MIC = 10, 20, 157, 410 \mu M$). Interestingly, their antimicrobial activity was much stronger than the antibiotic cefixime ($MIC = 35410 \mu M$) [42].

Fig. 5. Scheme of the preparation of triazole derivatives of menthol (**12–14**) [42]

2.2. Bioconjugates with antiparasitic effect

Corrales et al. efficiently synthesized novel triazole derivatives of cholic acid and 6-thiopurine (fig. 6). The conjugates obtained (**15–19**) were tested for their biological activity and cytotoxicity. Research *in vivo* confirmed their antimalarial efficacy far superior

to chloroquine (a substance used in patients diagnosed with malaria). Conjugate (**19**) was more effective than chloroquine on the 7th day of the study and all other compounds after 12 days. On the other hand, the tests performed *in vivo* indicate their action against Leishman's parasite. Most importantly, the resulting compounds are not toxic to mammalian cells [43, 44].

Fig. 6. Steroid-purine conjugates (**15–19**) with anti-leishmanial activity [43, 44]

The amino choline-bile acid compounds (**20–23**) exhibit exceptional activity against Leishman's parasite and *Mycobacterium tuberculosis* (fig. 7). Conjugate (**20**) exhibits a similar inhibitory effect against *M. tuberculosis* (MIC = 8.8 μ M) as available antituberculosis drugs. Biological testing of all structures (**21–23**) confirms their activity towards *promastigote* and *amastigote* *L. major* as well as leishmanicidal and antituberculosis properties [45].

Fig. 7. 1,2,3-triazole derivatives of cholic acid with aminocholine (**21–23**) [45]

2.3. Anticancer bioconjugates

Agarwal et al. designed novel bile acid and nucleoside molecules linked by a 1,2,3-triazole linker with antitumor activity (fig. 8). Studies have been carried out *in vitro* against three cancer cell lines (PC-3, MCF-7, IMR-32). Tests have shown that compounds (25) and (27) are characterized by the highest efficacy of MCF-7 ($IC_{50} = 8.084 \mu M$) and IMR-32 ($IC_{50} = 8.71 \mu M$) cells. It is worth noting that all compounds were tested for cytotoxicity and antituberculosis activity. Compound (28) has significant antituberculosis activity ($MIC = 4.09 \mu M$), while all compounds are not toxic to the human kidney [46].

Fig. 8. Steroid-nucleoside conjugates (24–31) [46]

Incredible anticancer activity is distinguished by dendrimers called “molecular pockets”. Efficient synthesis of first-generation dendrimers (chlorodendrimers) was developed, which were subsequently appropriately converted into second-generation azidodendrimers (fig. 9). On the other hand, the bile acid molecule was effectively enriched with an alkyne group. Finally, triazole derivatives (34–35) exhibited MTT activity against C6 glioma cells ($IC_{50} = 10.48 \mu M$) [47].

Fig. 9. Scheme of the synthesis of “molecular pockets” (**34–35**) [47]

Jurášek et al. described ribbon-type steroid dimers linked by a heterocyclic cholic acid moiety (**37**), ethienoic acid (**38**), or estrone (fig. 10). Appropriately modified reactants were subjected to a “click” reaction. The obtained 1,2,3-triazole derivatives showed antitumor activity against several cell lines. Compound (**37**) was effective against CCRF-CEM and K562 lines ($\text{IC}_{50} = 5.4$ and $5.35\text{ }\mu\text{M}$), and compound (**38**) against K562 and CEM-DNR-BULK ($\text{IC}_{50} = 5.37$ and $5.48\text{ }\mu\text{M}$) [48].

Fig. 10. Ribbon-type steroid dimers (**37–38**) [48]

Designed deoxyadenosine 1,2,3-triazole bile acid derivatives have been studied for activity against leukaemia (Jurkat and K562), colorectal (HCT116), ovarian (A2780), and human skin fibroblasts. Multistage bile acid and deoxyadenosine structure transformations were carried out [49, 50]. As a result, 1,2,3-triazole conjugates (**39–41**) (fig. 11). Compound (**40**) distinguishes the highest anticancer activity against cells of the K562 ($IC_{50} = 8.51 \pm 4.05 \mu M$) and Jurkat ($IC_{50} = 10.47 \pm 2.64 \mu M$) lines. In addition, compounds (**39**) and (**41**) are also active against K562 and Jurkat ($IC_{50} = 172.36 \pm 9.60 \mu M$, $35.86 \pm 11.60 \mu M$, $35.65 \pm 2.23 \mu M$ and $36.17 \pm 1.51 \mu M$, respectively) [51].

Fig. 11. Bile acid derivatives with deoxyadenosine (**39–41**) [49–51]

Subsequently, Perrone's research group synthesized bile acid conjugates-nucleoside with a C-3 and C-24 triazolyl bond (fig. 12). Their activity against human leukaemia cells (K562), colon cancer (HCT116), and skin fibroblasts (FIBRO) was determined. Unfortunately, their activity was low, so the structures were enriched with adenosine, deoxyadenosine, and deoxyuridine (fig. 13). The acid-deoxyadenosine compound (**53**) was efficacious against K562 ($IC_{50} = 8.5 \pm 4.0 \mu M$). Against C-3 of the triazolyl-linked bile acid-adenosine conjugate (**54**) was found to be effective against K562 and HCT116 (IC_{50}

of $43.5 \pm 1.3 \mu\text{M}$ and $23.1 \pm 1.7 \mu\text{M}$). For triazolyl junctions, C-24 was active (**49**), where the IC_{50} was $16.2 \pm 2.2 \mu\text{M}$ and $17.0 \pm 2.5 \mu\text{M}$ against K562 and HCT116, respectively. For (**50**), an activity of $23.6 \pm 1.2 \mu\text{M}$ for K562 only was determined. For bile acid–deoxyuridine compounds (**55–56**), the IC_{50} for K562 and HCT116 at $21.5 \pm 2.0 \mu\text{M}$ and $23.5 \pm 1.6 \mu\text{M}$, respectively. Moreover, for C-24 triazolyl compounds (**51–52**), the activity against $2.9 \pm 1.9 \mu\text{M}$ and $24.8 \pm 1.5 \mu\text{M}$, respectively [52].

Fig. 12. Scheme of the synthesis of C-3 (**46**, **48**) and C-24 (**44**) triazolyl linked bile acid-nucleoside conjugates [52]

Fig. 13. Steroid-nucleoside conjugates (**49–56**) with anticancer activity [52]

New triazolyl steroid-nucleoside conjugates were tested to evaluate their activity against human cell lines for prostate cancer (PC-3), breast cancer (MCF-7), neuroblastoma (IMR-32), and toxicity against human renal embryo (HEK 293 T) (fig. 14). In addition, their antituberculosis activity against *M. tuberculosis* H37Rv (strain ATCC 27.294) confirmed. Multistep synthesized conjugates (**57–65**) were compared with the activity of doxorubicin against MCF-7 ($IC_{50} = 0.44 \pm 0.05 \mu M$) and IMR-32 ($IC_{50} = 0.043 \pm 0.05 \mu M$) cells. Compounds (**65**) and (**60**) showed apoptosis for these cells, where their IC_{50} values were $8.71 \mu M$ and $8.08 \mu M$, respectively. Moreover, they did not destroy human HEK293 T kidney cells [46].

Fig. 14. Triazolyl conjugates deoxycholic/cholic-nucleoside acid (**57–65**) [46]

The synthesis of bile acids combined with triazolyl aryl ketones with antitumor properties against human breast cancer cells (MCF7) and mouse breast cancer cells (4 T1) was also developed (fig. 15). In the studies, it was assessed that the conjugate (**66**) is effective against MCF7 at $IC_{50} = 2.61 \pm 0,70 \mu M$, a (**67**) at $IC_{50} = 5.71 \pm 1.00 \mu M$. In addition, compound (**68**) also exhibits activity against T1 cells ($IC_{50} = 8.76 \pm 1.29 \mu M$). All conjugates (**66–68**) were not toxic to HEK293. Moreover, the study determined higher apoptosis in MCF-7 for compound (**68**) than (**66**). In the case of four T1 cells, apoptosis was similar for both compounds. In addition, it was found that the addition of cholic acid and the absence of aryl ketone substitution significantly increased the biological activity of the obtained molecules [53].

Fig. 15. Triazolyl aryl ketones derivatives of bile acids (**66–68**) [53]

2.4. Other types of bile acid bioconjugates with biological potential

The synthesis of novel bile acid dimers and sterols with a unit of 1,2,3-triazole (**69–74**) (fig. 16) was carried out. A complete spectroscopic analysis (^1H NMR, ^{13}C NMR, FT-IR), spectrometric (ESI-MS), molecular docking and calculations semi-empirically were performed. Research *in silico* indicates their biological activity [54].

Fig. 16. Dimers of bile acids and sterols (**69–74**) [54]

3. Conclusions

This review briefly presents the advances in synthesizing novel bile acid conjugates containing 1,2,3-triazole systems with antibacterial, antiparasitic, and anticancer properties. The research focuses on various microbial strains and cancer cell lines. The presented

research results shed new light on the design of syntheses in the search for new drugs.

ABSTRACT

Conjugates of steroids and other natural bioactive molecules (such as amino acids or carbohydrates) have proven promising compounds with diverse biological effects. This literature review summarises the importance of steroid conjugates in a broad spectrum of therapeutic applications. Steroid conjugates exhibit improved pharmacokinetic properties, improved target specificity, and reduced side effects compared to the parent compounds. This increases their clinical usefulness. Their versatility extends to drug delivery systems, enabling precise modulation of drug release kinetics and bioavailability. Moreover, steroid conjugates are vital in treating inflammatory and neurodegenerative diseases, hormonal disorders, cancer therapy, and combating microbial infections. The review presents the current state of research on steroid conjugates, highlighting the crucial role of steroid conjugates in modern medicine and their potential to revolutionise therapeutic paradigms and improve patient outcomes. Steroid compounds are excellent for developing agents with better bioavailability and are used as drug carriers or hydrogelators.

1. Introduction

Nature is a vast source of biologically active heterocycles with varying degrees of optimisation. Molecules derived naturally from biosynthetic pathways exhibit diverse physical, chemical, and biological properties [1,2]. The decreasing effectiveness of therapeutic agents due to their poor solubility, instability, or host resistance forces the search for new drugs. Coupling a carrier molecule with a biologically active substance has many benefits, such as systemic non-toxicity, minimisation of side effects, and overcoming drug resistance of target cells [3,4].

The conjugation of two biologically active molecules has influenced the enormous development of biomedicine, materials science, and pharmaceutical sciences [5–8]. A bioconjugate should be understood as a structure of two or more molecular units with different biological properties. With this technique, the molecule formed gains a double benefit by combining the properties of individual units, thus acquiring new activity [9,10]. Literature data indicate that steroid bioconjugates have the most excellent application in improved biomolecules with pharmacological potential [11–14].

Fig. 1 shows the different conjugation approaches to form new compounds known in the literature (Fig. 1). Bioconjugates are formed by

reactions between functional groups on other molecules or by a cross-linking agent. Cross-linking agents such as EDC (*1-Ethyl-3-(3-(Dimethylamino)propyl)Carbodiimide hydrochloride*) and DCC (*Dicyclohexyl Carbodiimide*) are used to form covalent bonds without an extra atom. Small molecule coupling controls the selectivity and toxicity of bioconjugates. The basic idea of bioconjugation is to connect molecules through covalent bonds. At least one of the molecules must be of biological origin or be part of a biomolecule [9]. Antibody-drug conjugates are therapeutic agents in which antibodies are conjugated with biologically active drugs. The FDA (*U.S. Food and Drug Administration*) has approved three such conjugates; more than 40 are in clinical trials [8]. Among these compounds, it is worth distinguishing between PEGylated (*Polyethylene Glycol*) adenosine deaminase (Adagen) used in the treatment of severe immunodeficiency and PEGylated L-asparaginase (Oncaspar, acute lymphoblastic leukaemia) [15]. In addition, other approved conjugates are m.in, Pegintron, Pegasus, Neulasta, and Mylotarg [16–19]. It is worth noting that among the antibody-drug couplings, anticancer drugs such as Adcetris (treatment of Hodgkin lymphoma) and Kadcyla (therapy of breast cancer) deserve special attention [20,21].

Steroids include a group of natural compounds found in all eukaryotic cells. These compounds are characterised by a rigid four-ring cyclopentanoperhydrophenanthrene framework (Fig. 2),

Fig. 1. Selected pathways of molecule bioconjugation.

hydrophobicity, varying degrees of functionalisation, and amphipathic properties [22]. Among steroids, bile acids (e.g. lithocholic acid, deoxycholic acid, cholic acid), plant (e.g. stigmasterol) and animal (e.g. cholesterol) sterols, corticosteroids (e.g. cortisol), sex hormones (e.g. progesterone, androgens) and sapogenin (e.g. sarsasapogenin) deserve special attention. The most important functions of bile acids include the absorption and control of lipid and glucose metabolism [23]. Corticosteroids play a crucial role in carbohydrate metabolism and regulating inflammation. On the other hand, sex hormones such as estrone, pregnenolone, or testosterone are responsible for the proper functioning of the entire body [24,25].

Due to the enormous diversity of biological and physicochemical properties, steroids have become an excellent choice for bioorganic synthesis [26,27]. Transformations of functional groups through the formation of ester, ether, or amide bonds consistently produce new derivatives (Fig. 1). However, additional groups may change

pharmacokinetic properties (e.g. lipophilicity, solubility) and pharmacodynamic properties (e.g. receptor selectivity). As lipophilic compounds, they can easily cross cell membranes (e.g. blood–brain barrier), which is crucial in the design of steroid drugs. Introducing polar groups can change their lipophilicity, affecting the distribution in the body and the duration of action. It is worth noting that a slight transformation of the steroid molecule causes a massive change in biological systems. The rigid structure of the steroid nucleus makes it easier for them to penetrate the cell and, consequently, to interact with a specific hormone receptor. Steroids are characterised by particular stereochemistry (spatial arrangement), crucial for interacting with protein receptors. Minor differences in stereochemistry can determine the activity of the drug, namely whether it will be an agonist, antagonist, or inactive. The *cis/trans* configuration between the rings, especially A/B, also plays a significant role in receptor binding specificity. Several structural and biological characteristics of steroids have influenced their use in drug design [28–30]. Some known steroid conjugates increase the expression of genes of essential transport proteins. Also fundamental are derivatives with anticancer, antibacterial, antifungal, antimicrobial, antiviral (including HIV), anticoagulant, anti-inflammatory, antioxidant or insecticidal (pesticides) activity [31–46]. Moreover, they have neuro-protective potential in Alzheimer's disease and affect transcription factors [47].

Recently, several reviews have been published highlighting the diverse therapeutic benefits of steroid and amino acid conjugates and bile acids with bioactive molecules [48,49]. Research on the therapeutic use of steroid bioconjugates in cancer therapy is intensively conducted, confirmed by numerous scientific reports [50,51]. Therefore, we decided to comprehensively review structurally diverse steroid bioconjugates that may have potential therapeutic relevance. PubChem, Web of Science, Scopus and Reaxys databases were searched for studies on the multidirectional biocidal activity of steroid conjugates with natural compounds from the last two decades (2004–2024). The focus was on specific terms such as „steroid conjugates”, „amino acid

Fig. 2. Selected steroid compounds (1–11).

conjugates”, „bile acid bioconjugates”, „anticancer agents”, or „biocidal activity”. The most critical aspect was experimental articles, while theoretical and review articles were considered to have supplementary scientific value. This review covers the diverse biological applications of steroid bioconjugates and may benefit the broader scientific community searching for new drugs. It is worth mentioning that the dominant position was taken by steroid-amino acid conjugates that can be used as antimicrobials or in chemotherapy [52,53].

2. Steroid conjugates of anticancer significance

Recently, scientists have emphasised the design of steroid conjugates with anticancer properties (see Table 2). An exciting approach is developing compounds acting as enzyme inhibitors crucial for steroid metabolism, such as steroid sulfatase (STS) and hydroxysteroid dehydrogenase (HSD). STS inhibitors, such as Irosustat, have been studied in the context of breast and endometrial cancer due to their ability to inhibit estrogen metabolism, leading to the inhibition of tumour cell proliferation [54]. In turn, HSD inhibitors, including 17 β -HSD1 inhibitors, are being analysed as potential anticancer agents, especially in cases of steroid-dependent cancer (prostate cancer) [55]. Additionally, steroid conjugates can act by binding to receptors (e.g. antiestrogens or antiprogesterones), making them multi-targeted tools in anticancer therapy. Antiestrogens, such as tamoxifen, are widely used in the treatment of estrogen-dependent breast cancer [56]. Antiprogesterins (such as mifepristone) have shown promising results in the context of hormone-dependent cancers, including endometrial and ovarian cancer [57]. Simultaneous blockade of steroid-metabolising enzymes and tumor-promoting receptors allows for multi-level effects on cancer cells. Steroid coupling is aimed at obtaining a less toxic structure and, at the same time, has high bioavailability. Therefore, the development of steroid conjugates is considered a promising therapeutic strategy in the treatment of hormone-dependent cancers.

2.1. Steroid conjugates with doxorubicin

Estrogens contribute to the development of breast cancer. The mammary gland produces more type β cells than type α . Whereas breast cancer cells do the complete opposite and overexpress abnormal α -type cells. This significant difference has provoked interest in estrogens as potential transport vehicles for cytotoxic agents. Initial attempts to bind estrogen to anthracyclines were unsuccessful. Only coupling the C-3 and

C-17 positions of estradiol with doxorubicin via an amide bond brought better results. Conjugate (12) (Fig. 3) was effective against MCF-7 cells ($IC_{50} = 0.7 \mu M$, doxorubicin $IC_{50} = 0.5 \mu M$). In addition, the estradiol derivative showed 10-fold lower activity against ER-negative breast cancer cells and K562 leukaemia cells ($IC_{50} = 10.5 \mu M$) [58].

Chaikomom et al., on the other hand, synthesised a compound between dexamethasone and doxorubicin called DexDOX (13) (Fig. 3). The critical step in this reaction was the extremely simple conjugation of the 3' amino group of doxorubicin with a dexamethasone molecule. DexDOX showed comparatively lower cytotoxicity than doxorubicin against MCF-7 cells ($IC_{50} = 90.3$ and $2.8 \mu g/ml$, respectively). However, based on the results of flow cytometry analysis, a clear difference was found in the mechanism of cytotoxicity of these two compounds. Moreover, the lipophilicity of dexamethasone resulted in greater cellular penetration of the conjugate than doxorubicin alone. On the other hand, it suppressed the effects of P-gp overexpression, which is why it showed high potential for therapy for treating drug-resistant cancers [59].

2.2. Carbohydrate derivatives

Steroid glycosides comprise glycone (a sugar radical) and an aglycone (a steroid radical). They have been used in the treatment of congestive heart failure. Literature reports indicate their increasing cytotoxicity against many cancer cell lines [60]. Dioscine (14) (Fig. 4) inhibits the development of HL-60 leukemia cells. In addition, it has antiviral, antifungal, and anti-inflammatory properties [61]. Isolated from the roots *Polygonatum zanlanscianense* saponins were characterised by an IC_{50} of $5.06 \mu g/ml$ against HeLa cells [62]. In contrast, other saponins derived from the plant *Myriophyllum extensum* K. Schum. differ in the presence of an unsaturated lactone ring at C-17 β . This feature of structure is crucial for anticancer properties. This is why extensumside A (15) (Fig. 4) showed IC_{50} in the range of 0.29 to $0.47 \mu g/ml$ against several cancer cell lines (including the highest efficacy against A549 cells). Extensumside B was inactive due to the lack of a lactone ring [63]. This highlights the importance of steroid saponins as natural hybrids for drug discovery.

Mimaki et al. successfully isolated and identified a cholestane glycoside (16) (Fig. 5) from onion *Ornithogalum saundersiae*. Studies have shown that OSW-1 has much higher activity against HL-60 cancer cells than etoposide or Adriamycin [64]. Many low-yield attempts have been made to synthesise this natural compound (using sugars such as D-xylose or L-arabinose) [65,66]. In addition, due to the cytotoxicity of cholestane glycoside, it was necessary to modify its structure. As a result, several transformations were made, such as replacing cholestane with estrane (conjugate with $IC_{50} = 0.43$ – $0.7 \mu M$) or synthesising OSW-1 analogues of 22-deoxy-23-oxa [67,68]. Artificial steroid glycosides (17–18) (Fig. 5), in which the length of the side cholesteryl chain was increased to 8–11 carbon atoms, were characterised by low IC_{50} values (i.e. from 6.1 to $8 nM$) for CEM and G361 cells.

Other compounds with antiproliferative activity were the dansyl derivatives of polyphyllin D and dioscin. Conjugate obtained (19) (Fig. 5) and its analogues showed activity against HeLa cells ($IC_{50} = 15$ – $18 \mu M$), as well as formed self-assembled micelles [69].

It is worth noting that for the HeLa cell tumour line, cytotoxic was also created by the CuAAC method (Copper(I)-Catalyzed Alkyne Cycloaddition) (20) (Fig. 6). The bioconjugate of secosterone monosaccharide -D- exhibited an IC_{50} of $20 \mu M$, which is almost twice as low as standard cisplatin ($IC_{50} = 42.6 \mu M$). It has been proven that the presence of acetylated carbohydrates and oxime in part of the secosteroid affects anticancer activity [70].

2.3. Alkaloid and curcumin conjugates

Liu et al. designed the synthesis of taxols linked to hyaluronic acid, folic acid, monoclonal antibodies, and 3,17 β -estradiol. They aimed to improve solubility and increase selectivity against ER-positive breast

Fig. 3. A conjugate of doxorubicin with estradiol (12) and dexamethasone (13).

Fig. 4. Dioscine (14) and extensumside A (15) are cytotoxic to cancer cell lines.

Fig. 5. Steroid glycosides (16–19) with biological activity.

Fig. 6. The conjugate (20) was obtained by the CuAAC method.

cancer. Conjugation was used via bonds at C-2', C-7 or C-10 in the taxol moiety with the C-11 or C-16 position in the steroid moiety. Bioconjugate (21) (Fig. 7) was distinguished by the highest effectiveness (IC₅₀ = 40 nM against MCF-7), as was the estradiol analogue substituted

in the C-11 position. On the other hand, taxol modified at the C-7 position showed good activity against the PC-3 cell line (IC₅₀ = 1.7–4.2 μM). Studies have confirmed higher anticancer efficacy against ER-α positive cell lines but still lower than for the parent taxol (IC₅₀ for taxol against MCF-7 and MDA-31 cells was 4.9 and 4.5 nM, respectively) [71].

Curcumin encapsulated in liposomes as a cationic lipid based on cholesterol and curcumin (23) (Fig. 7). Following synthesis, Apiratikul et al. performed antitumor activity tests for several cancer cell lines, such as HeLa, A549 (epithelial lung adenoma), HepG2 (liver cancer), K562 (erythromyeloblastoid leukaemia) and 1301 (T-cell lymphoblastic leukaemia), as well as for the human kidney (HEK293). Encapsulated curcumin was safe for regular human embryonic kidney cells. It has also been found to have up to 8 times higher cytotoxic activity than ordinary curcumin (22). Although the efficacy of encapsulated curcumin was not as high as expected, the results were in the IC₅₀ range of 3.1–10 μM (see Table 1) [72].

2.4. Steroid-amino acid conjugates

Platinum complexes are of great importance as agents used in chemotherapy. Kvasnica et al. described the synthesis of platinum (II) conjugate with steroidal esters of L-methionine and L-histidine. The corresponding steroid esters were synthesised by esterification of Boc-protected amino acids with the hydroxyl group of various steroids (such as cholesterol, diosgenin, etc.). The Boc group was then removed using trifluoroacetic acid. Platinum(II) complexes were obtained by reacting the resulting steroid esters with potassium tetrachloroplatinate in aqueous dimethylformamide. Amphiphilicity cholesterol and estrone were used. The steroid part had the function of transporting the active substance to the breast cancer cells. Research *in vitro* showed that the platinum (II) complex of estrone with L-methionine (24) (Fig. 8) has a destructive effect on CEM cells (IC₅₀ = 14 and 20 μmol/L). Among other compounds, pregnenolone esters (25, 26) (Fig. 8) with L-methionine and L-histidine. Their effectiveness against CEM cells oscillated around IC₅₀ = 18–23 μmol/L. It is worth noting that all the obtained complexes were not toxic to normal human fibroblasts [73].

A synthesised cholesterol-phosphotyrosine conjugate (27) (Fig. 9) was evaluated to determine its properties against HeLa cancer cell lines and platinum-resistant AC780cis cells. Compound (28) had efficacy at IC₅₀ = 16 and 13 μM against HeLa and AC780cis, respectively (where

Fig. 7. Taxol derivative (21) and cholesterol-based curcumin and cationic lipid structure (23).

Table 1

Anticancer activity of curcumin and its encapsulated steroid derivative (23).

Compound	IC ₅₀ (μM)				
	HeLa	A549	HepG2	K562	1301
Curcumin	17	50	30	20	8
23	8	10	4	2,5	3,1
Empty liposomes	180	210	105	165	90

IC₅₀ = 71 μM for cisplatin). In addition, studies suggest that enzyme dephosphorylation affects apoptosis. The dephosphorylated compound (28) (Fig. 9) showed lower activity against AC780cis (IC₅₀ = 50 μM) [74].

Fusidic acid (29) (Fig. 10) is an antibiotic effective in treating bacterial infections, especially of the skin. It may have anticancer effects, especially when combined with amino acids. The synthesis focused mainly on the protection of the acid group of fusidic acid by esterification with benzyl bromide. The next step included coupling with Boc-protected amino acids (such as glycine, alanine, leucine, and lysine). The obtained conjugates were converted into hydrochloride salts using HCl in dioxane. Studies on fusidic acid derivatives have demonstrated their anticancer activity against various cancer cell lines, such as cervical cancer (HeLa), glioma (U87), multidrug-resistant epidermal oral carcinoma (KBV), and gastric cancer (MKN45). Compound (33) (Fig. 10) proved to be the most promising, showing excellent activity against all cancer cell lines tested (cell viability 8 %, 18 %, 9 %, and 8 %, respectively). Compounds (30) and (32) (Fig. 10) induced apoptosis of KBV and HeLa cells less than 30 %, while compound (31) was ineffective only against MKN54 (less than 33 % for other cell lines) [75].

Aromatic amide derivatives of bile acids and amino acids (34–38) (Fig. 11) were obtained (using HOBt and EDC-HCl) to test their antiproliferative properties against colon (HT29), breast (MDAMB231), and glioma (U87MG) cancers. They were also tested for cytotoxicity to the human normal kidney cell line (HEK293T). Better selectivity from cisplatin against breast cancer cell lines was shown by phenyl (34), benzothiazole (35), and 4-methylphenyl (37) derivatives (IC₅₀ = 1.35, 1.41 and 4.52 μM, respectively). On the other hand, bile acid derivatives (36–38) distinguished activity against U87MG cells in the range of 1.62–2.49 μM (for doxorubicin IC₅₀ = 2.60 μM, for cisplatin IC₅₀ = 3.60 μM). Almost all the compounds were non-toxic to an average human

HEK293T cell line (at a concentration of 25 μM). Moreover, bile acid conjugates containing an aryl group in the side chain were more active than heteroaryl derivatives [76].

Another critical group of steroids is the phytosterols, which are components of plant membranes (Fig. 12). These compounds, isolated mainly from vegetable oils, are involved in the proper growth of plants and lower blood cholesterol levels. Most importantly, phytosterols prevent the production of carcinogenic compounds, prevent the development of cancer cells, and cause their apoptosis [77]. Several conjugates of γ -oryzanol (43) (Fig. 12) were obtained by conjugation of the 4-hydroxyl ferulate ester γ -oryzanol with fatty acids, phenolic acids, amino acids, lipoic acid, retinoic acid, curcumin, and *trans*-resveratrol. A C-3 bond was also formed in the steroid backbone of selected phytosterols, such as cycloartenol (39), 24-methylene cycloartenol (40), campesterol (41), and β -sitosterol (42) (Fig. 12). All new structures were tested for anticancer activity, among other things. Studies have shown that phytosterol conjugated with cystine (44) has activity against HeLa and DAOY cells (where IC₅₀ ranges from 1.4 to 8.3 μM; for γ -oryzanol IC₅₀ > 10 μM) [78].

Chang et al. designed the efficient synthesis of lithocholic acid-amino acid conjugates acting as potential inhibitors of the enzyme sialyltransferase. Sialyltransferase is involved in hypersialylation. It is a crucial biological process during cancer cell metastasis, invasion, cell adhesion, or immune defence [79]. The tests performed showed that the conjugates (45–47) (Fig. 13) have enzyme inhibitory activity at IC₅₀ of 6, 7, and 5 μM, respectively [80].

The CuAAC reaction was also used to synthesise triazolyl-13 α -estrone conjugates with nucleosides. The multi-step synthesis included, among others, the reaction of the nucleoside protected with the 5-O-(4,4-dimethoxy trityl (DMTr)) group with acetic anhydride in pyridine, then deprotection with boron trifluoride in a solution of hexafluoroisopropanol and nitromethane, tosylation with tosyl chloride in pyridine at room temperature. Finally, after tosyl-azide substitution in DMF at 50 °C, the azide was formed, which was subjected to a click reaction with 3-O-propargyl-13 α -estrone in the presence of DIPEA and a solvent. To obtain triazole conjugates of 13 α -estrone with the nucleoside, the acyl derivative was deprotected in an ammonia solution in methanol at 50 °C. Interestingly, an adequately protected cytidine derivative (48) (Fig. 14) was more active than the unprotected thymidine derivative (49) (IC₅₀ = 9.0–10.4 μM and 19 μM, respectively) versus

Table 2
Anticancer activity of steroid-based bioconjugates.

Type of steroid's conjugate	Bioactive compounds	Cell lines	Activity (IC ₅₀)	References

17β-HSD1. However, it is worth noting that 13α-estrone showed a higher inhibitory potential than all estrone-nucleoside conjugates [81].

Similar triazole bile acid-nucleoside bioconjugates were developed by Navacchia et al., and their antiproliferative activity against K562, HCT116 cancer cells, and normal human skin fibroblast cells were

studied. The conjugate (50) (dU-nor-CDC) (Fig. 14) was effective against K562 cells (IC₅₀ = 42.9 μM), whereas the compound (51) (dU-UDC) caused apoptosis of both cancer cell lines (IC₅₀ = 16.5 and 22.0 μM) [82].

Perrone et al. developed and synthesised bile acid and deoxy-adenosine conjugates linked by a triazole system (52–54) (Fig. 15). The three-step synthesis of 3α-azido bile acid derivatives began with the reaction of their methyl esters with iodine and triphenylphosphine in the presence of imidazole and 1,3-dioxolane. These compounds were then reacted with NaN₃ in DMF to form 3α-azido derivatives. Alkenyl deoxyadenosine derivatives were obtained from 8-bromodeoxyadenosine and hexynothiol in the presence of a palladium catalyst. Finally,

3α-azido bile acid derivatives were coupled with alkenyl deoxyadenosine derivatives using CuSO₄·5H₂O, sodium ascorbate, and THF: *t*-BuOH: H₂O (room temperature or microwave at 50 °C) to form the corresponding 1,2,3-triazole conjugates (52–54). The modification of the C-3 position of the steroid part was aimed at assessing the antitumour activity of the obtained structures. Compound (53) with the highest cytotoxicity against leukaemia cancer cells, K562 and Jurkat, had an IC₅₀ of 8.51 ± 4.05 μM and 10.47 ± 2.64 μM, respectively [83,84]. Interestingly, other literature reports indicate that deoxyadenosine conjugated only with chenodeoxycholic acid has a better apoptotic effect on the K562 cell line (IC₅₀ = 16.2 ± 2.2 μM) than its triazole derivative [82].

2.5. Steroid and rhodamine B conjugates

Chemotherapy-induced cell death can be induced in various ways. Studies show that mitochondria are vital in deciding whether a cell survives or dies [85]. There is growing interest in agents that directly target mitochondria and induce controlled cell death, called mitocans. Dysfunction of the mitochondria is associated with many diseases, including neurodegenerative, metabolic and cardiovascular diseases [86].

Rhodamine B, known mainly as a natural biosensor, is being studied for its potential anticancer properties. One of the mechanisms of its action is the induction of oxidative stress in cancer cells, leading to programmed cell death. This compound can be a scaffold for the formation of bioactive cationic molecules. The mitochondrial membranes of cancer cells have a higher membrane potential than non-cancer cells. Mitocans with a lipophilic cation, such as the rhodamine structure, show high selectivity for these cells [87].

Serbian et al. described the synthesis of steroid conjugates based on testosterone, prednisone, and abiraterone with rhodamine B (Fig. 16) [88]. In the coupling reaction, rhodamine B acyl chloride was coupled with steroids by adding triethylamine in dichloromethane (DCM). The conjugates (55–57) underwent cytotoxicity studies against several human cancer cell lines. They were shown to be active in the low μM to nM range. The testosterone conjugate (55) had an EC₅₀ of 59 nM against MCF-7 cancer cells and acted mainly through necrosis. In contrast, the prednisone conjugate (56) was less cytotoxic (EC₅₀ = 0.2 μM) but mostly worked through apoptosis. Interestingly, the compound showed higher selectivity for A2780 cancer cells than NIH 3 T3 fibroblasts. In contrast, the rhodamine B derivative and abiraterone (57) showed average cytotoxicity and selectivity.

3. Steroid conjugates with antibacterial and antifungal activity

The increasing drug resistance of bacteria to antibiotics and constant mutations force scientists to look for analogues of active substances available on the market (Table 3). One of the first natural antibiotics was squalamine (58) (Fig. 17). This natural conjugate of sterol and spermidine was extracted from the stomach of spinyfin *Squalus acanthias*. Squalamine has a biocidal effect on Gram-positive and Gram-negative bacteria, resulting in cell death [89]. Attempts have been made to synthesise its analogues, so squalamine is considered the beginning of

Fig. 8. Anticancer derivatives of estrone (24) and pregnenolone (25, 26).

Fig. 10. Fusidic acid (29) and its benzyl derivatives with amino acids (30–33).

steroid conjugate chemistry [90–92].

Novel chiral amides of amino alcohols, cholic acid, and deoxycholic acid were synthesised to test them for antimicrobial activity. Hazra et al. found that the bioconjugate of deoxycholic acid and (-R)-2-amino-cyclohexanol (**62**) (Fig. 18) is toxic to most Gram-positive bacteria (especially *E. coli* ATCC 25922 and *S. aureus* ATCC 25923, with MIC = 45 and 15 µg/ml, respectively) [93]. In contrast, another compound (1R, 2R)-1-phenyl-2-deoxycholicacetamidopropane-1,3-diol) was active against the pathogenic fungus, where IC₅₀ = 62.5 µg/ml.

Mishra et al. investigated the characterisation of eight new amide derivatives of chloramphenicol (**63–70**) (Fig. 19) [94]. This natural antibiotic has been extracted from actinomycete *Streptomyces venezuelae*. To synthesise steroid-amino alcohol conjugates, deoxycholic acids, cholic acid, (1R,2R)-1-phenyl-2-amino-1,3-propanediol, (1S,2S)-1-phenyl-2-amino-1,3-propanediol, (1R,2R)-1-*para*-nitrophenyl-2-amino-1,3-propanediol, (1S,2S)-1-*para*-nitrophenyl-2-amino-1,3-propanediol, were used. Biocidal activity tests against Gram-positive and Gram-negative bacteria showed deoxycholic acid conjugates (**68**) and (**70**) (IC₅₀ < 60 µg/ml), particularly for the *Cryptococcus neoformans*.

Vatmurge et al. developed a conjugation of bile acids with β-lactam

Fig. 11. Aromatic amide derivatives of cholic acid (34–38).

rings via ester or amide bonds. Antibiotics containing the azetidine-2-one unit are widely known. The conjugate created (71) (Fig. 20) was most active against yeasts *Yarrowia lipolytica* (8 µg/ml) as well as against fungal strains *Candida albicans* (128 µg/ml) and *Benjaminiella poitrasii* (32 µg/ml). The amide conjugate was characterised by efficacy at concentrations of 16, 8, and 32 µg/ml against *C. albicans*, *B. poitrasii*, and *Y. lipolytica* [95].

A series of aminocholestanes combined with an imidazole or pyridine ring was described by Kim et al. *in vitro* demonstrated that the link (72) (Fig. 20) caused the death of several strains of bacteria *S. aureus* (MIC < 4 µg/ml). In contrast, the 3,7-di(imidazole) steroid exhibited intense antibacterial activity against most bacterial cells at MIC ~ 4 µg/ml [96].

Cationic amphiphilic conjugates of cholic acid and lysine also exhibited antibacterial properties. The conjugate (73) (Fig. 20) was active against *S. aureus*, *E. coli*, and *C. albicans* with MIC < 8 µg/ml. Researchers also observed that another cholic acid derivative exhibited antibacterial potential against resistant strains *S. aureus* 1704, *E. coli* 4052, and *Candida auris*. Most importantly, the compound (73) was safe for erythrocytes, causing changes only in the cell membranes of microbial strains [97].

Tetrapeptides glycine and β-alanine combined with cholic acid in position C-3β (74–77) (Fig. 21) with antibiotic properties comparable to fluconazole or erythromycin (FIC < 0.5 against *E. coli* and *C. albicans*) [98]. On the other hand, the scientific report of Yadav et al. shows that the peptide derivative of cholic acid with valine and glycine (78) (Fig. 21) exhibit antimicrobial activity against bacterial strains *E. coli*, *Klebsiella pneumoniae*, and *Acinetobacter baumannii* (MIC₉₉ = 4, 8 and 4 µM, respectively) [53,99].

Amphiphilicity plays a vital role in the destruction of biological membranes of microbes. Kong et al. extracted a steroid amino acid from an Irish sea sponge *Polymastia boletiformis*. After evaluation of antimicrobial activity (disc test, 1/4 in.), it was found that the conjugate (79) (Fig. 22) was toxic to strains *S. aureus*, *C. albicans*, and *Pythium ultimum* (MIC = 100, 75, and 25 µg/disc, respectively) [100]. Recent literature

reports indicate that isolated analogs of steroid amino acids (81,82) (Fig. 22) were active against fungi of the genus *Cladosporium cucumerinum* (1D and 2D analysis of NMR, ZOI = 8.0 mm and 10.1 mm at 60 and 30 µg/disc, respectively). The conjugate activity (82) was the highest against *C. albicans*, with the ZOI being 9.8 mm (100 µg/disc) [101].

Tuberculosis (TB) is a deadly infectious disease that, despite being wholly cured with short-term therapy, is becoming increasingly resistant to available anti-tuberculosis drugs. Consequently, this leads to multidrug-resistant tuberculosis (MDR-TB). Using corticosteroids with a functional hydroxyl group at the C11 position is beneficial, especially in severe central nervous system or pericardial involvement cases. Steroid hormones with biological activity, such as fluticasone or dexamethasone, are an important therapeutic option [102]. Researchers seeking to develop effective inhibitors for *Mycobacterium tuberculosis* focused on bile acid derivatives with a substituted hydroxyl group at the C-11α position. It has been shown that compounds (83) and (84) (Fig. 23) show significant stunted growth in *M. tuberculosis* at a concentration of 30 µg/ml [103]. This is a decisive step in the fight against this dangerous disease.

4. Steroid conjugates with antiviral activity

HIV and AIDS continue to pose a considerable challenge to medicine. According to the World Health Organization (WHO), in 2022, about 39 million people were HIV positive, including 1.5 million children [96]. Although this virus no longer takes such a deadly toll, new therapeutic agents are still being sought [104].

Mayaux et al. developed the synthesis of betulinic acid (triterpenoid with a steroid-like skeleton) conjugates to assess their HIV-inhibiting activity. It was found that the selectivity and effectiveness of the obtained molecules depended to a large extent on their structural characteristics, especially on the length of the side chain. Therefore, the highest inhibitory activity of HIV replication was assessed for the compound (85) (gamma amino acid, a derivative of (3S,4S)-4-amino-3-hydroxy-6-methylheptanoic acid) (Fig. 24) at a concentration lower than

Fig. 12. Phytosterol analogues with antitumor activity (39–44).

Fig. 13. Lithocholic acid conjugates (45–47) as sialyltransferase inhibitors.

0.02 $\mu\text{g}/\text{ml}$ [105].

Bile acids' transport properties were used in synthesising cholic acid conjugates with small molecule peptides. Compounds (86–88) (Fig. 24) were investigated to determine their HIV-1 protease inhibitory capacity. The modification of the steroid backbone consisted of attaching the peptide part to the C-24 position. Tests showed that the compound β -benzyl-D-aspartic acid (88) had a moderate HIV-1 protease inhibitory potential ($\text{IC}_{50} = 125 \mu\text{M}$) [106].

Another type of deadly disease is the measles virus. Despite the availability of vaccines containing the measles antigen virus (MV), it is a

common cause of death among children. MV's hemagglutinin glycoprotein (H) activates the cell membrane and facilitates viral penetration. Immunogenic H protein triggers an immune response. Scientific reports report that the hemagglutinin loop (HNE) epitope on the H protein (sequence H386-395 CKGKIQALCE) has an amphiphilic loop-like structure with an embedded disulfide bridge [107,108].

Vaccines containing peptides with the core sequence HNE, cystine, and a steroid nucleus were designed. The rigid steroid system provided the proper conformation for peptide coupling. As a result, the newly formed molecule resembled a loop with amphiphilic properties. An

Fig. 14. Triazole steroid conjugates (48–51) as anticancer agents.

Fig. 15. Bile acid-deoxyadenosine conjugates linked by a triazole system (52–54).

Fig. 16. Rhodamine B steroid esters (55–57).

appropriately protected bile acid derivative (89) was modified with a photolabile linker to obtain a compound (90) (Fig. 25). A series of successive selective transformations (such as group deprotection and finally coupling with a Gln-Ala-Cys-Lys tetrapeptide the same as the MV-HNE sequence) of the C-3 and C-12 positions of the steroid led to the production of a target macrocyclic peptidosteroid (91) (Fig. 25) [109]. This compound was supposed to be a precursor for new measles vaccines. Subsequently, Bode et al. synthesised a similar peptidosteroid (89) (Fig. 25) containing an additional disulfide bond (as in the HNE loop of the measles virus). The conjugate (92) had better bioavailability and stability than linear peptides. Subsequent studies have found that

this macrocyclic compound also exhibits increased binding affinity for the monoclonal antibodies BH216 and BH21 compared to linear and non-steroidal peptides [110]. Therefore, the conjugate (92) can be considered a breakthrough in the design of vaccines to prevent the measles virus.

Yang et al. described and synthesised dehydroepiandrosterone (DHEA) conjugates with potential activity against H1N1 and H3N2 type A (IAV) influenza viruses. Bioconjugate containing 2-OH-Ph residue (93) (Fig. 26) inhibited viral RNA synthesis and protein expression. Based on the MTT test, it was concluded that the compound (93) was most effective at $CC_{50} = 111 \pm 7.1 \mu\text{g/ml}$ [111].

Yang et al. report further effective thiazoline conjugates based on their promising activity against steroid-derived DNA and RNA viruses [39]. Assessment *in vitro* demonstrated that the link (94) (Fig. 26) was cytotoxic to enterovirus 71 (EV71) and Coxsackie B3 virus (CVB3). The results were compared with antiviral agents such as ribavirin and pyridavir ($IC_{50} = 1327$ and 836 ; 431 and $397 \mu\text{mol/l}$, respectively). Again, based on the MTT test, it was found that the DHEA derivative (94) exhibits activity against RD and Hep-2 cells at $IC_{50} = 305.3$ and $44.7 \mu\text{mol/l}$, respectively. The legitimate antiviral properties of dehydroepiandrosterone bioconjugates place it at the forefront of potential antiviral drugs.

		affinity for hASBT	K _i = 35 x M	

Acyclovir (**95**) (Fig. 27) is a medicine used to inhibit the herpes virus [112]. Poor absorption in the intestine and low oral bioavailability (about 20 %) were the impetus for the design of its new derivative. Valacyclovir (**96**) (Fig. 27) is an ester derivative of L-valine with much better therapeutic potential [113]. Bile acid conjugation with valacyclovir resulted in a total of 4 novel prodrugs. Tests *in vitro* with esterase in HBSS showed that after two hours, acyclovir was again obtained from the prodrug [114,115].

In 2004, Tolle-Sander et al. developed similar analogues of acyclovir and valine-linked bile acids. Assessment *in vitro* and *in vivo* demonstrated that the prodrug acyclovir valylchenodeoxycholate (**97**) (Fig. 27) was characterised by an affinity for hASBT (i.e., a human sodium-dependent apical bile acid transporter) comparable to cholic acid (K_i = 35 x M and

Fig. 17. Structures of squalamine (**58**) and its modified analogues (**59–61**).

Fig. 18. Bioconjugate of deoxycholic acid and (-R)-2-aminocyclohexanol (**62**).

K_i = 25 x M, respectively). Most importantly, the steroidal acyclovir conjugate was about 16 times more selective for hASBT-COS cells than acyclovir alone. In addition, acyclovir valineoxycholate showed significantly stronger passive permeability. On the other hand, an assessment of oral bioavailability in rats showed that the compound (**97**) is twice the bioavailability of acyclovir [116].

5. Anti-inflammatory steroid conjugates

The pharmacological potential of glucocorticoids is used to treat many autoimmune diseases, asthma, intestinal disorders, and rheumatoid arthritis. The consequence of frequent use of steroids may be the occurrence of osteoporosis or a decrease in the immunity of the immune system [117,118].

Efforts to develop more safe and effective anti-inflammatory drugs have led to the development of so-called „anti-drugs“. Loteprednol etabonate can be applied topically [119]. Once they enter the

Fig. 19. Bile acid and chloramphenicol conjugates (63–70) with biocidal activity.

Fig. 20. Conjugates (71–73) with antibacterial and antifungal properties.

bloodstream, the „anti-drugs” are converted into inactive metabolites and are removed from the body [120]. The final molecule is formed by conjugating steroidal „anti-drugs” with non-steroidal anti-inflammatory drugs. Specific conjugates have been synthesised to prevent a potential

increase in potency, such as the combination of prednisolone with non-steroidal anti-inflammatory medications such as indomethacin and ibuprofen [121]. Biological studies of ibuprofen-prednisolone conjugate (98) (Fig. 28) showed a slight increase in anti-inflammatory effects

Fig. 21. Tetrapeptides and dipeptides of cholic acid and amino acids (74–78).

Fig. 22. Natural steroid amino acids (79–82) with antimicrobial activity.

Fig. 23. Bile acid derivatives (83–84) as tuberculosis factor inhibitors.

(62.5 % inhibition) compared to prednisolone alone. In contrast, indomethacin and prednisolone bioconjugate did not show systemic anti-inflammatory activity.

Liu et al. designed steroid hybrids with C₆₀ to determine their anti-inflammatory properties [122]. Tests *in vivo* in mice showed that a dexamethasone derivative (99) (Fig. 29) eliminated the swelling

initiated by xylene administration in 47 % [123]. Hydrophobic steroid scaffolds have been used as carriers of selective oligonucleotides in gene therapy [124]. Thus, the second generation of micellar cholesterol polyamidoamine (100) (Fig. 29) conjugated to resveratrol and the heme oxygenase-1 (HO-1, pDNA) gene [125]. Its therapeutic potential for treating acute lung injury (ALI) was then evaluated. Studies in an animal

liposaccharide (LPS)-induced ALI model showed that the conjugate (100) containing the drug and pDNA reduces the production of cytokines (critical micelle concentration of 0.22 mg/ml^{-1}). Subsequent reports have found that polyamidoamine and cholesterol micelles similar to curcumin and the HO-1 gene also reduce the levels of pro-inflammatory cytokines [126].

6. Steroid conjugates as antioxidant agents

Fullerenes (common C_{60} molecules or radical sponges) are effective at scavenging free radicals, which is why they are used as pharmacological antioxidants [127]. Due to their low solubility in polar and non-polar solvents, it is necessary to modify them. Multiple interfaces of

Fig. 27. Acyclovir (95) and its derivative (96–97) with chenodeoxycholic acid.

Fig. 28. A conjugate of prednisolone and ibuprofen (98) with anti-inflammatory activity.

fullerenes with steroids, amino acids, and peptides were performed to improve solubility and increase interaction with the membrane and interior of the target cell [128–130]. Bioconjugate (101) (Fig. 30) containing a linker of γ -aminobutyric acid (GABA) between estradiol and fulleropyrrolidine showed 3 times higher antioxidant activity ($ED_{50} = 20.2 \mu M$) than fullerene alone ($ED_{50} = 64.1 \mu M$) [131]. The improved antioxidant properties of the carbon clusters resulted from a lipophilic steroid system, which was also confirmed by morphological, electrochemical, and theoretical analyses [132].

7. Steroid conjugates in anticoagulant therapy

Heparin is an effective anticoagulant drug composed of glycosaminoglycans weighing about 15 kDa. Unfractionated heparin (UFH) is

Fig. 29. A derivative of dexamethasone (99) and cholesterol (100) with potential use in anti-inflammatory drugs.

Fig. 30. A steroid conjugate of fullerene (**101**) with antioxidant properties.

administered intravenously and subcutaneously with low molecular weight heparin (LMWH). UFH works by binding to antithrombin III, strongly inhibiting the action of thrombin (unlike LMWH) and factor X_a [133]. Heparins are conjugated with lipids and other molecules to increase oral bioavailability by modifying free groups (such as sulfate, carboxylic, hydroxyl, or amine) [134]. Studies suggest that the DOCA-heparin conjugate (**102**) (Fig. 31) has a higher bioactivity than the cholesterol-heparin conjugate [135–137]. In addition, increased intestinal absorption was confirmed for the bis-DOCA-heparin conjugate (**103**) (Fig. 31) [138]. Preclinical studies *in vivo* showed that the conjugate (**102**) is safe and non-mutagenic [36]. The DOCA-heparin conjugate containing the ethylenediamine linker between the carboxyl groups positively affected wound recovery after surgery (anticoagulant activity = 86 IU/mg) [139]. Similar anticoagulant properties are possessed by the conjugate (**104**) (109.8 IU/mg) (Fig. 31). On the other hand, for the LMWH-tetraDOCA compound, an increase in oral bioavailability (19.9 %) and anticoagulant activity (33.5 %) was observed [140]. Literature data indicate that a dose of 5 mg/kg (for mice) inhibits thrombosis formation during cancer [141].

8. Steroid conjugates as glucocorticoid antagonists

11 β -hydroxysteroid dehydrogenases (11 β HSD, including 11 β HSD1 and 11 β HSD2) are responsible for the proper level of glucocorticoids in the body. Excessive production of these enzymes interferes with converting cortisone to cortisol (or *vice versa*), leading to metabolic syndrome or fatty liver without obesity [142]. Inhibition of 11 β HSD2 leads to cortisol activating mineralocorticoid receptors, which retain sodium and water [143]. 11 β HSD2 inhibitors are used in patients on

hemodialysis to prevent potassium loss caused by cortisol activation of MR in the colon [144]. MR activation can adversely affect the heart and metabolism [145]. Inhibition of 11 β HSD is a promising direction in the treatment of atherosclerosis, osteoporosis, hyperlipidemia, and type 2 diabetes. This is why MR antagonists and 11 β HSD inhibitors are needed. Progesterone and its metabolites bind to MR and inhibit 11 β HSD [146,147]. The conjugation of amino acids and 11 α -hydroxyprogesterone by modification at the 11 β position yielded compounds (**105–107**) (Fig. 32). The conjugates were found to be suitable inhibitors of 11 β HSD2 (IC₅₀ = 2.41; 2.69 and 6.76 μ M), although they did not match the inhibitory activity of 11 α -hydroxyprogesterone (IC₅₀ = 0.40 μ M) [148].

9. Insulin-stimulating steroid conjugates

Insulin is a hormone produced by the beta cells of the pancreas. Its primary function is to regulate blood glucose levels. Insulin allows the body's cells to absorb glucose from the blood and use it as energy. In addition, it supports the storage of glucose in the liver as glycogen and inhibits the breakdown of fats. Insulin deficiency, or the body's improper response to this hormone, leads to diabetes [149,150].

The deoxycholic acid-insulin derivative (**109**) (Fig. 32) was synthesised using the succinimide deoxycholate ester. In contrast, conjugation with the same amino group of the Lys residue^{B29} insulin through the succinimide bisdeoxycholy-1-lysine ester (**108**) (Fig. 33) has given a link (**109**). Lee et al. found that the attachment of a large molecule of steroid acid did not affect insulin structure and the persistence of binding to insulin receptors on HepG2 cells. The results indicated that steroidal insulin conjugates are characterised by prolonged interaction with the body. Moreover, they were more active longer and did not break down faster than native insulin. The report shows that for the conjugate (**109**), the insulin receptor IC₅₀ was 3.37×10^{-9} M, for conjugate (**110**) (Fig. 33) was 2.24×10^{-9} M, and for native insulin 1.28×10^{-9} M [151]. Bile acid derivatives may act as potential therapeutic agents during abnormal insulin secretion.

10. Sarsasapogenin conjugates in the treatment of neurodegenerative diseases

Alzheimer's disease is a chronic and progressive neurodegenerative disease. It manifests as a gradual loss of cognitive functions such as memory, thinking, orientation, and the ability to perform daily activities independently. It is the most common cause of dementia among the

Fig. 31. Heparin steroid conjugates (**102–104**) as potential anticoagulants.

Fig. 33. Insulin steroid conjugates (108–110).

elderly. Characteristic symptoms are memory disorders, speech problems, confusion, and changes in personality and behaviour. In the brain of people with Alzheimer's, there is a build-up of amyloid plaques and neurofibrillary plexuses. As a result, nerve cells become damaged and die. The causes of the disease are not fully understood. Treatment focuses mainly on alleviating symptoms and slowing their progression [152]. Natural steroid conjugates have greatly improved the treatment of this disease (see Table 4) [153].

Table 4
Potential biological properties of steroid-based conjugates.

Type of steroid's conjugate	Number of bioactive compounds	Bioactivity	References
Steroid-ibuprofen	98	anti-inflammatory,	[121]
Dexamethasone derivative	99	inhibition of swelling	[123]
Liposaccharide-steroid	100	cute lung injury-ALI (reduced cytokine production, MIC = 0.22 mg/ml)	[125,126]

	110	insulin receptor (2.24 * 10 ⁻⁹ M)	
Sarsasapogenin-amino acid	111	neuroprotective activity	[47]
	112	against the SH-SH5Y	
	113	(Alzheimer's disease)	
	114		
	115		
Bile acid-amino acid	116	inhibitor NAFLD	[158]

Sarsasapogenin isolates neurons that are vulnerable to damage from hydrogen peroxide. Studies on an animal model have also shown that it can minimise memory loss [154]. In combination with 3-carbamate, it has a neuroprotective effect [155].

The conjugates of sarsasapogenin (**11**) (Fig. 2) with the C-26 amino acid methyl ester (**111–115**) (Fig. 34) were synthesised to determine their neuroprotective activity against the SH-SH5Y cell line. Derivative (**115**) conjugated to phenylalanine at position C-26 had almost 4 times stronger neuroprotective properties than sarsasapogenin (102.2 % and 27.3 %, respectively). As a result of such significant neuroprotective activity of the conjugate (**115**) was found to minimise peroxide-induced neuronal apoptosis by inhibiting the activity of cleaved poly(ADP-ribose) polymerase (PARP for short) and cleaved caspase-3. In addition, such an effect also increases the expression of neurotrophic brain factor (BDNF), as well as its receptor tyrosine kinase B (TrkB). Compounds with the methoxyl group at the C-3 position showed the highest neuroprotective potential. Wang et al. suggest that the resulting sarsasapogenin conjugates may be of breakthrough importance for patients with Alzheimer's disease [47].

11. Steroid conjugates for the treatment of liver damage

Fatty liver, or non-alcoholic steatohepatitis (NASH), is an incurable type of non-alcoholic fatty liver disease (NAFLD). It is known that the main effects of NAFLD are hepatocellular carcinoma (HCC), cirrhosis of the liver, and end-stage liver disease [156]. Due to the coupling between

Fig. 34. Conjugates of sarsasapogenin and amino acids (**111–115**) with promising activity in treating Alzheimer's disease.

bile acid receptor G (TGR5) and farnesoid X receptor (FXR) ligands, bile acids have great potential in the treatment of NAFLD [157].

Chenodeoxycholic acid L-arginine ethyl ester bioconjugate (CDCArg) (116) (Fig. 35) was tested in a mouse model to determine its cytotoxicity as well as its effect on cholesterol accumulation in the liver [158]. Voloshin et al. suggest that adding the CDCArg compound to the diet of high-fat mice does not cause excess cholesterol in the liver and its destruction. It has also been observed that the conjugate (116) protects the liver and prevents weight gain. Steroidal amino acid conjugates can be precursors as therapeutic agents in inhibiting NAFLD.

12. Steroid conjugates as organic gels

Organogels are gels in which an organic solvent is used as a dispersing medium for the three-dimensional lattice formed by gelling molecules. These are soft materials that have both liquid and solid properties. Steroid amino acids can be crucial in the formation of organogels. Due to their unique structural and chemical properties, steroid amino acids can act as effective gelling molecules. They can stabilise the structure of organogels through intermolecular interactions such as hydrogen bonding, van der Waal's, or hydrophobic interactions. Biocompatible steroid amino acids have a vast potential due to the ability to customise the gel structure to meet specific needs.

Conjugates of bile acid methyl esters and L-methionine (117–119) (Fig. 36) were evaluated for gelling properties in several organic solvents. It was concluded that the compound (117) was highly susceptible to gelation. On the other hand, the association (119) formed strong and colourless gels. In addition, X-ray powder diffraction tests have shown that temperature reduction to -150°C affects reversible conformational changes in the solid state of the conjugate (117) [159].

Svobodova et al. synthesised stigmaterol derivatives with amino acids (120–122) (Fig. 37) [160]. Amino acids (glycine, L-leucine, L-phenylalanine) were adequately secured at the N-terminus of Fmoc, which was then removed using piperidine. Then, after conjugation with stigmaterol, hydrochloride salts (123–125) were formed to investigate their gelling potential against derivatives of other amines compared to inert phytosterols. Tests showed that stigmaterol amino acid conjugates exhibited significant gelling properties. It was also observed that there were gel-forming salts only under polar alcoholic conditions (such as stigmaterol hydrochloride with glycine and L-taurine) and those with the ability to form gels only under non-polar aromatic conditions (stigmaterol hydrochloride with L-phenylalanine).

In the literature, bile and amino acids conjugates with gelling activity are also known [161]. Phenylalanine conformers conjugated urea compounds to bile acids. The most minor crystal structure was shown by

Fig. 36. Bile acid and L-methionine conjugates (117–119) with gelling properties.

the cholic acid conjugate (128) (Fig. 38). Based on the results of the analyses (DSC, powder XRD, or ^{13}C NMR from the solid phase), it was found that the polymorphism of cholic acid derivatives (128) and (129) (Fig. 38) affects their broad organogelling potential. In addition, all derivatives of lithocholic, deoxycholic, and cholic acids showed better-gelling properties in 1,2-disubstituted aromatic solvents (e.g., 1,2-dimethylbenzene) compared to solvents substituted in position 1,3 or 1,4.

Based on the good gelling properties of bile acid amino acids, Maitra et al. designed further derivatives of α -amino acids [162]. Conjugate hydrochlorides (130–137) (Fig. 39) were synthesised using ethyl chloroformate. It was determined that the obtained structures showed good hydrogelling properties at pH within the range of 7–8 as molecules with low mass and appropriate hydrophilic-hydrophobic balance. This rigid structure has been used to synthesise gold and ZnO nanoparticles.

Finally, the Maitra research group published a report on the behaviour of bile acid-based gelling agents with glycine and phenylalanine (138–139) (Fig. 40) depending on the pH [163,164]. Interestingly, deoxycholic and cholic acid derivatives did not form gels, probably due to the presence of additional hydroxyl groups. A hydrogel matrix of a derivative of lithocholic acid was used to synthesise silver and gold nanoparticles. A photoreduction analysis was performed to document the immobilisation of these nanoparticles on gels, compounds (138), and (139). A silver-doped conjugate (138) is resistant to colour change caused by exposure to solar radiation. On the other hand, after adding NaBH_3CN and after one minute, the silver-doped compound (139) turned pink, and after 1 h, it turned dark pink and finally yellow.

13. Conclusions

Due to their structure and multidirectional biological profile, steroid compounds have long attracted interest in bioorganic chemistry. Conjugates of steroids with diverse groups, such as polyamines, amino acids, carbohydrates, bioactive heterocycles and bis-conjugates, show significant pharmacological potential. This review discusses numerous conjugates of these compounds with bioactive molecules and diverse biological activity. The derivatives are primarily focused on combating cancers, pathogens and microorganisms. There are also examples in the literature of bioconjugates acting on metabolic disorders and performing antioxidant or antithrombotic functions. These compounds are excellent materials for designing new molecules with improved bioavailability. They can act as drug carriers or be used as hydrogels. Future studies should focus on further exploration of new conjugation techniques. They will allow us to overcome the current limitations related to bioavailability and selectivity of action. Furthermore, additional research could focus on therapeutic applications in treating metabolic diseases. The development of multi-target conjugates is also crucial. This could significantly increase the effectiveness and safety of therapy for many serious diseases.

Supporting Information

ABSTRACT: Molecules originating from natural sources are physicochemically and biologically diverse. The conjugation of two active biomolecules has become the foundation for medical and pharmaceutical sciences. An effective synthesis of 11 new steroid-pyrimidine conjugates containing 1,2,3-triazole rings was carried out. The group of 3α -OH bile acids (lithocholic, deoxycholic, cholic) and 3β -OH sterols (cholesterol, cholestanol) were respectively modified to azidoacetates. 2-thiouracil was converted into N(1)S and N(3)S dipropargyl derivatives. Azide-alkyne cycloaddition in the presence of copper(I) of the obtained compounds led to the preparation of 1,2,3-triazole derivatives. Based on a series of spectroscopic (^1H NMR, ^{13}C NMR, Fourier-transform infrared (FT-IR)), spectrometric analyses (Electrospray ionization-mass spectrometry (ESI-MS), electron impact-mass spectrometry (EI-MS)), and semiempirical calculations, the structures of all compounds were confirmed. *In silico* biological tests and molecular docking (for domain 1KZN, 2H94, 5VSZ, 1EZF, 2Q85) were performed for selected compounds. The tests performed indicate the theoretical antimicrobial potential of the obtained ligands.

1. INTRODUCTION

Two highly significant classes of natural compounds, pyrimidine bases and steroids, are pivotal in numerous biological processes. Among these, thio derivatives of pyrimidine bases such as 2-thiouracil emerge as noteworthy constituents of t-RNA.^{1,2} Beyond their role in biological systems, these compounds have made substantial contributions to the realms of pharmacology, medicine, and medicinal chemistry. Their S-, N-, or S, N-disubstituted analogues have displayed notable therapeutic potential, mainly exhibiting antiviral, antithyroid, and antitumor activities.^{3–6} They have also been identified as valuable in biosensing applications and radioprotectors.^{7,8} Nucleobases have been found to have broad applications as precursors capable of forming strong hydrogen bonds in the design of new biomaterials or complex nanostructures.^{9,10}

The prototropic tautomerism exhibited by thio derivatives of pyrimidine bases has garnered significant interest (Scheme 1). The equilibrium between tautomeric forms, particularly in the case of 2-thiouracil, plays a pivotal role in dictating its chemoselectivity and regioselectivity. Moreover, this equilibrium is intricately influenced by factors such as temperature and the physical state of the compound, whether in solution or the solid phase.¹¹

Steroids are essential for medicinal chemistry because they involve all metabolic pathways. The rigid skeleton of cyclopentanoperhydrophenanthrene provides steroid conjugates with

the proper arrangement of other molecules and several physicochemical properties.¹² Bile acids act as an emulsifier, helping with the digestion and absorption of fats, while sterols such as cholesterol are essential for cell structure and the biosynthesis of steroid hormones.^{13,14} Modifications of functional groups such as 3α -OH, 7α -OH, 12α -OH or 3β -OH and amphiphilic properties resulted in their wide use in bioorganic synthesis.¹⁵ Their 1,2,3-triazole derivatives with anticancer properties are particularly important.^{16,17} These compounds can inhibit the growth of cancer cells through various mechanisms, such as induction of apoptosis, blocking DNA synthesis, or inhibiting angiogenesis.^{18–20} Some studies suggest that bile acid derivatives with 1,2,3-triazole systems may have antiviral activity. They may inhibit viral replication or penetration into host cells.^{21,22} Moreover, they have been used as potential drugs in treating cholestasis and research tools for studying the mechanisms of drug action, especially in the context of interactions with cell receptors and signaling pathways.^{23–25}

Scheme 3. Synthesis of Substituted Derivatives of Methyl Esters of Bile Acids (9–11) and Sterols (14–15)

The main route for the synthesis of 1,2,3-triazole derivatives is the “click” chemistry reaction. This technique involves the rapid, efficient, and specific formation of new chemical bonds between two reactants.²⁶ Typically, 1,3-dipolar reactions are used, such as the reactions of azides with alkynes in the presence of copper(I) ions, which lead to triazole linkers.²⁷ This method is beneficial in supramolecular chemistry, biochemistry, and nanotechnology, as well as in creating materials with advanced properties. Its advantages are ease and versatility, high reaction efficiency, and minor byproducts.^{28,29}

The combination of steroids with pyrimidines can lead to the creation of compounds with unique biological activity.³⁰ Conjugation of a carrier molecule with a biologically active substance brings many benefits, such as nontoxicity, minimizing side effects, and overcoming drug resistance of the target cell.³¹ These compounds may have therapeutic, anticancer, antiviral, anti-inflammatory, or neuroprotective effects.^{32–35} Steroid-pyrimidine conjugates may be more stable compared to uncombined components. Bile acid and uracil conjugates are

being investigated for their potential anticancer effects. Research suggests that these compounds may have antiproliferative and apoptotic activity against cancer cells, which opens the possibility of their use in anticancer therapy.^{36–38} Bile acid and uracil conjugates can be carriers in gene therapy. Thanks to their ability to bind to deoxyribonucleic acid (DNA), they can deliver genetic material to target cells, which opens the possibility of using them to treat genetic and cancer diseases. These are promising compounds with potential therapeutic applications in oncology, hepatology, virology, and gene therapy.^{39–42}

2. RESULTS AND DISCUSSION

2.1. Synthesis. The studies describe efficient syntheses of obtaining new steroid-pyridine bioconjugates linked by 1,2,3-triazole rings. Bile acids (lithocholic, deoxycholic, cholic), sterols (cholesterol, cholestanol) with appropriately modified 3 α - or 3 β -OCOCH₂N₃ groups, such as uracil and 2-thiouracil dipropargyl were used as a reactant. According to the literature,

Scheme 4. Synthesis of Steroids–pyrimidine Conjugates (16–26)

the synthesis of two propargyl derivatives of 2-thiouracil (*N*(1)*S* and *N*(3)*S*), as well as 11 new bile/sterol–pyrimidine conjugates containing 1,2,3-triazole systems, has not been described so far. The created compounds align with the modern trend of synthesis of macrocyclic systems, which are the foundation in the search for new structures with biological activity.

The structures of two propargyl disubstituted derivatives of 2-thiouracil (4) and (5), as well as all synthesized conjugates (16–26), were determined based on their ^1H and ^{13}C NMR, Fourier-transform infrared (FT-IR), electrospray ionization-mass spectrometry (ESI-MS), and electron impact-mass spectrometry (EI-MS) spectra. Moreover, the PMS calculation method was performed for all compounds. The syntheses of substrates (3–5), (9–11), (14–15), and conjugates (16–26) are shown in Schemes 2, 3, and 4, respectively.

2.2. Spectroscopic Characteristics. The structural characterization of all synthesized compounds was accomplished by analyzing their ^1H and ^{13}C NMR, FT-IR, ESI-MS, and EI-MS spectra. In addition, PMS calculations were conducted for each compound further to explore their properties and characteristics.^{43–45}

The six substrates: methyl 3 α -azidoacetox-5 β -cholan-24-oate (9), methyl 3 α -azidoacetox-12 α -acetox-5 β -cholan-24-oate (10), methyl 3 α -azidoacetox-7 α ,12 α -diacetox-5 β -cholan-24-oate (11), cholester-3 β -yl 2-azidoacetate (14), 5 α -cholestan-3 α -yl azidoethanoate (15) and *N*1, *N*3-bis(prop-2-yn-1-yl)uracil (3) have been described and characterized in the literature.^{46–48}

In the ^1H NMR spectrum of dipropargyl derivatives of 2-thiouracil (4, 5), characteristic doublets were observed at 8.30 and 7.77 ppm from CH-6 protons and at 6.50 and 6.26 from CH-5 (Figure 1). Signals from $\text{CH}_2\text{--N}(1)$ protons appear as double singlets at 5.03 and 4.85 ppm, similar to $\text{CH}_2\text{--S}$ protons at 4.02 and 3.91 ppm. In the 2.53–2.19 ppm range, characteristic triplets originating from $\text{C}\equiv\text{CH}$ protons were observed.

Diagnostic signals from protons from 1,2,3-triazole rings were observed for all conjugates (16–26) as singlets in the 7.90–7.70 ppm range (Figure 2). Characteristic doublets from protons at CH-6 and CH-5 were observed at 8.26–8.25 and 6.45 ppm (for compounds 22–24), 7.77–7.75 and 6.22–6.20 ppm (for compounds 19–21), 7.46–7.45 and 5.75–5.74 ppm (for compounds 16–18, 25, 26). Protons present in the methylene groups $\text{N--CH}_2\text{--triazole}$ ring and $\text{S--CH}_2\text{--triazole}$ ring give singlets with values of 5.54–5.52, respectively (*N*(3)), 5.34–5.33 (*N*(1)) and 4.56–4.50 ppm. Signals appeared in the ^1H NMR spectra of steroid–uracil conjugates (16–18, 25–26) at 5.25–5.23 and 5.13–5.11 ppm from protons of the CH_2 methylene groups connecting the steroid skeleton with the triazole ring. For compounds (19–24), similar singlets were observed at 5.15–5.08 ppm. In the ^1H NMR spectra of all compounds (16–26), there are characteristic multiplets in the 4.86–4.61 ppm belonging to 3' α -H and 3' β -H. Additionally, in the case of conjugates (17–18), (20–21), (23–24), a singlet appears from the 12' β -H proton at 5.11–5.09, while for (18), (21), (24) multiplets originating with the 7' β -H proton at 4.93–4.91 ppm. A cholesterol derivative (26) diagnostic is a broad singlet for C6'-H at 5.38 ppm. The proton spectra of all bile

Figure 1. Spectra ^1H NMR of new compounds (4) and (5).

acid–pyrimidine compounds are characterized by a singlet at 3.67–3.65 ppm coming from protons from the ester group CH_3 -25'. Moreover, for derivatives of deoxycholic and cholic acids, characteristic singlets from hydrogens present in the $7'\alpha$ - OCOCH_3 and $12'\alpha$ - OCOCH_3 groups can be observed at 2.15 and 2.11–2.09 ppm, respectively. In the ^1H NMR spectra of all compounds (16–26), signals coming at the hydrogens from the

methyl groups CH_3 -18', CH_3 -19', and CH_3 -21' were observed at 0.73–0.65, 1.04–0.90, and 0.93–0.91 ppm, respectively. Moreover, for sterol derivatives (25–26), doublets appear in the range of 0.86–0.85 ppm, characteristic of the CH_3 -26' and CH_3 -27' groups.

The ^{13}C NMR spectra of compounds (4) and (5) show signals from carbons $\text{C}(4)=\text{O}$, $\text{C}(2)-\text{S}$, $\text{C}(6)=(\text{C}5)$, at 169.8–

Figure 2. Diagnostic signals in spectra ¹H NMR conjugates (18, 20, 22).

Scheme 5. Fragmentation of Compounds (4) (a) and (5) (b) during EI-MS

160.7, 167.5–160.7, 157.8–151.9 and 110.8–104.1 ppm, respectively. Signals from $\text{C}\equiv\text{C}$ atoms were observed in the 79.7–70.5 ppm range, while signals from carbons from methylene groups CH_2 were observed in the 54.1–19.4 ppm range.

In the ^{13}C NMR spectra of all conjugates (16–26), signals from carbons from methyl groups C-18', C-21', and C-19' were observed about 12.4–11.8, 18.7–17.5, 23.0–20.8 ppm, and additionally for compounds (25, 26) at 21.2–19.2 ppm from atoms C-26' and C-27'. However, carbon atoms in the carbonyl group in positions 3' α (or 3' β)-OC=O resonate in the 165.7–165.4 ppm range. The carbon atoms of the 12' α -OC=O steroid skeleton gave signals in the range of 170.5–170.4 ppm. However, the carbon of the 7' α -OC=O gave a signal at 170.5–170.2 ppm. The signals of C(24')=O, C(4)=O, and C(2)-S appeared in the range of 174.7–174.5, 170.4–162.0, and 168.1–151.1 ppm, respectively. Moreover, unsaturated carbon atoms at the C(5)=C(6) bond can be seen at 111.0–102.0 and 157.6–142.4 ppm. However, the diagnostic carbon atoms from the triazole ring, such as C=CH, give signals at 145.7–138.8 and 125.4–123.3 ppm, respectively. On the other hand, the methylene carbon atom of the steroid skeleton- CH_2 -triazole ring was observed at 51.2–51.0 ppm.

2.3. Infrared Spectroscopy. The most characteristic feature of the FT-IR spectra of compound (4, 5) is the band at 3287–3228 cm^{-1} assigned to the $\nu(\equiv\text{C}-\text{CH})$ group. The steroid skeleton is a saturated hydrocarbon, so it does not provide many useful IR features. Stretching solid vibrations of C–H bonds are identified at 2972 and 2927 cm^{-1} . Additionally, for synthesis, the new compounds of thiouracil are requisite and analytical bands at 2122 cm^{-1} , which are specific attributes of $\nu(\text{C}\equiv\text{C})$ group. Moreover, for all products (16–26) are also observed two characteristic solid bands at 1748–1661 cm^{-1} and 1248–1211 cm^{-1} are assigned respectively to the symmetric

group $\nu(\text{C}=\text{O})$ and $\nu(\text{C}-\text{O})$. In addition, characteristic stretching vibrations of C–H bonds are present in 2965–2852 cm^{-1} .

2.4. Electron Impact Mass Spectrometry. In the $N(1)$ S substitution, there are ions with molecular masses of 107 and 97, which are not present in the $N(3)$ S substitution spectrum. The presence of the m/z 165 ion in $N(3)$ S with an intensity of 100% indicates the possibility of its formation in two ways mass fragmentation (Scheme 5).

2.5. Electrospray Ionization. The ESI-MS spectra were acquired using methanol as the solvent. In all instances, the molecular ion $[\text{M}]^+$ is detected, indicating the presence of a positively charged ion with a proton, alkali metals, or halides in positive ion mode (ES^+) as well as negative ion mode (ES^-).

Figure 3 displays the ESI-MS spectra of conjugates (16), (19), and (20). In this spectrum, ion peaks are observed at m/z at 1174 (20%) $[\text{C}_{64}\text{H}_{94}\text{N}_8\text{O}_{10} + \text{K}]^+$ and 1158 (100%) $[\text{C}_{64}\text{H}_{94}\text{N}_8\text{O}_{10} + \text{Na}]^+$ (compound 16), 1189 $[\text{C}_{64}\text{H}_{94}\text{N}_8\text{O}_9\text{S} + \text{K}]^+$ (10%) and 1174 (100%) $[\text{C}_{64}\text{H}_{94}\text{N}_8\text{O}_9\text{S} + \text{Na}]^+$ (compound 19), 1306 $[\text{C}_{68}\text{H}_{98}\text{N}_8\text{O}_{13}\text{S} + \text{K}]^+$ and 1290 (100%) $[\text{C}_{68}\text{H}_{98}\text{N}_8\text{O}_{13}\text{S} + \text{Na}]^+$ (compound 20).

2.6. PM5 Calculations. The PM5 semiempirical calculations were performed using the WinMopac 2003 program. The final heat of formation (HOF) of compounds (3, 4, 5) and conjugates (16–26) is presented in Table 1, and Figure 4 shows their molecular models. Theoretical values of calculations are very often used in comparing crystallographic structures or in determining molecular docking.

The obtained HOF values indicate that the most stable are triazole systems of cholic acid with uracil or thiouracil (18, 21, 24). This results from blocked hydroxyl groups in the steroid skeleton at the C-7' and C-12' atoms. Acetate groups (7' α -OAc and 12' α -OAc) predispose to the formation of intramolecular interactions, such as hydrogen bonds or electrostatic inter-

Figure 3. ESI-MS spectra of bioconjugates (16), (19), and (20).

Table 1. Heat of Formation [kcal/mol] of Compounds (3, 4, 5) and (16–26)

compound	heat of formation [kcal/mol]
3	28.9829
4	97.0622

^aThe values are given in x, y, and z coordinates and the Angstrom unit.

lithocholic acid (16, 19, 22) and sterols (25, 26). This is due to the lack of additional groups to create stable interactions. Moreover, due to the C5′=C6′ double bond, the cholesterol conjugate (25) has a higher HOF value than the cholestanol conjugate (26). The positive HOF values for compounds (3, 4, 5) result from two propargyl groups in each molecule. Alkyne bonds make uracil/thiouracil derivatives the least stable and can be easily modified.

2.7. Prediction of Activity Spectra for Substances. The pharmacological activities of the synthesized compounds were determined using the *in silico* Prediction of Activity Spectra for Substances (PASS) program, which is based on computer analysis of structure–activity relationships. This program uses a heterogeneous training set containing approximately 250,000 biologically active compounds from various chemical series, covering approximately 4500 different types of biological activity. Because PASS only requires the structural formula of a chemical compound to predict, it can be used in the early stages of research. Many examples of successful applications of PASS have led to the development of new pharmacological agents.^{49–52} This program is also helpful in studying the biological activity of secondary metabolites. The present study focused on the activities predicted with the highest probability for a potential compound (focal activities).

Biological activity prediction analysis could only be performed for compounds whose mass does not exceed 1200 g/mol. Therefore, the potential pharmacotherapeutic properties of two new propargyl thiouracil derivatives (4 and 5) and conjugates (16, 19, 22, 25, 26) have been described. Table 2 lists the target

compounds against which the conjugates show the highest probability of biological activity. According to the research results, the most frequently predicted types of activity for compounds (4) and (5) are proteasome ATPase inhibitor, electron-transferring-flavoprotein dehydrogenase inhibitor, muramoyltetrapeptide carboxypeptidase inhibitor and chloride peroxidase inhibitor. However, *in silico* tests for the new steroid-pyrimidine conjugates (16, 19, 22, 25, 26) obtained show the highest activity against glyceryl-ether monooxygenase inhibitor, alkylacetylgllycerophosphatase inhibitor, antieczematic, cytoprotectant and CYP17 inhibitor. The obtained triazole derivatives show different biological activity than thiouracil substrates. Their predicted effects can be used in the design of hypolipemic, antispot, cholesterol-lowering and even prostate cancer treatments.

2.8. Molecular Docking. The molecular docking process started by converting the SMILES⁵³ representation of conjugated chemical structures (new ligands) into three-dimensional (3D) structures, and the Gasteiger⁵⁴ charges were added to each new ligand. It was accomplished through the application of OpenBabel tool version 3.1.1.^{55,56} Subsequently, the protein domains corresponding to the PDB⁵⁷ IDs 1EZF^{58,59} 1KZN,^{60,61} 2H94,^{62,63} 2Q85^{64,65} and SVSZ^{66,67} were prepared in accordance with the standard AutoDock tool 1.5.7 scheme.⁶⁸ Molecular dockings were then carried out using AutoDock Vina,⁶⁹ with the specific parameters outlined in Table 3 for each docking search.

The determination of molecular docking centers was based on the ligands in the raw PDB files.⁷⁰ UCSF Chimera software,

version 1.1670, was employed to visualize the three-dimensional aspects.

2.9. Selected Protein Domains. Their specific biological functions guided the selection of protein domains within the physiological system:

- antifungal activity (PDB IDs: 1EZF, 5VSZ)
- antibacterial activity (PDB IDs: 1KZN, 2Q85)
- Both antifungal and antibacterial activity (PDB ID: 2H94)

These proteins belong to different enzyme classes:⁷¹

- transferases (1EZF) - transfer specific functional groups from one molecule to another
- isomerases (1KZN) - facilitate intramolecular rearrangements within a single molecule
- oxidoreductases (2H94, 2Q85, and 5VSZ) - catalyze oxidation–reduction reactions by transferring electrons between molecules

The protein domain 1EZF⁵⁸ corresponds to squalene synthase, which catalyzes squalene production, a precursor to ergosterol, an essential component of fungal cell membranes. Inhibiting squalene synthase disrupts ergosterol biosynthesis, making it a classic target for antifungal drugs. Understanding the structure and function of squalene synthase aids in developing antifungal agents to combat fungal infections.^{59,72}

The protein domain 1KZN,⁶⁰ known as gyrase, is crucial in bacterial DNA replication and transcription by catalyzing negative supercoiling of circular DNA. Targeting DNA gyrase with antibacterial agents can lead to bacterial death. Compounds like quinolones, coumarins, and cyclothialidines have been developed to inhibit gyrase, offering potential avenues for antibacterial drug discovery.^{61,73}

The protein domain 2H94⁶² shows the shape of a human enzyme called Lysine-Specific Demethylase-1 (LSD1). This enzyme helps control how genes are turned on or off by removing certain chemical marks from proteins called histones. These marks are like little tags on the histone tails. Interestingly, the products of this enzyme can also have antifungal properties. Some bacteria and fungi depend on specific chemical reactions for their survival. By interfering with these reactions, the LSD1 enzyme can slow down the growth of these microbes.^{63,74}

The protein domain 2Q85⁶⁴ corresponds to *Escherichia coli* MurB, associated with antibacterial activity. MurB is an enzyme involved in the peptidoglycan biosynthesis pathway of bacteria, making it a potential target for antibacterial agents. Inhibiting MurB could disrupt bacterial cell wall formation, leading to bacterial death.^{65,75,76}

The protein domain 5VSZ⁶⁶ represents the structure of CYP51 from the pathogen *Candida albicans*, known as lanosterol 14 α -demethylase (LDM). LDM is the target of azole drugs used to treat fungal infections, but their efficacy is limited by drug resistance and suboptimal cure rates, especially in immunocompromised patients. Understanding the structure of CYP51 aids in developing new antifungal agents to combat drug-resistant fungal pathogens and improve treatment outcomes for fungal infections.^{67,76,77}

2.10. Similarities and Differences between Novel and Endogenous Ligands. To visualize the differences between native ligand and new ligands, the molecular some of QED (Quantitative Estimate of Druglikeness)⁷⁸ descriptors were calculated with RDKit python library,⁸⁰ as shown in Table 4.

Both the native and new ligands exhibit a wide range of molecular weights. The new ligands have more molecular weight

Table 4. Comparison of Native Ligands and New Ligand Molecular Descriptors

name	molecular weight [g/mol]	HB acceptors	HB donors	polar surface area Å ²	<i>a</i> log <i>P</i>	rotatable bonds
1EZF	539	7	3	133.24	1.09	9

20	1268	19	0	254.11	10.17	21
21	1384	23	0	306.71	9.25	23
22	1152	15	0	201.51	11.09	19
23	1268	19	0	254.11	10.17	21
24	1384	23	0	306.71	9.25	23
25	1128	10	0	158.02	13.20	20
26	1132	10	0	158.02	13.36	20

than the native ligands. The number of hydrogen bonds acceptors of new ligands is similar to the number of hydrogen bonds acceptors in native ligands. In the case of hydrogen bonds donors, the new ligands do not have any of them. The polar surface area is generally higher than in the case of new ligands. The lipophilicity is much different for the new ligands exposed to higher *a*log*P* values.⁷⁹ It indicates that new ligands are exhibiting much higher lipophilicity compared to native ligands, which may lead to low solubility and poor absorption.⁸⁰ There is also variability in the number of rotatable bonds, meaning that the flexibility of the ligands is different. To conclude, it can be said that the new ligands are not very similar to native ligands. Thus, they can be potent ligands that do good activity.

2.11. Molecular Docking. The RMSD (Root-Mean-Square Deviation) values of atomic positions are provided in Table 5.

Table 5. Quantitative Assessment of the Structural Differences between the Endogenous Ligands Raw Pose and the Endogenous Ligands Predicted Pose through Molecular Docking

PDB ID	1EZF	1KZN	2H94	2Q85	5VSZ
RMSD (Å)	1.30	0.50	0.54	1.54	1.65

RMSD measures the average distance between the atoms of two superimposed molecules. It is commonly used to quantify the structural similarity between two molecules in space. In the context of molecular docking, RMSD describes how far the predicted pose of a ligand differs from the native pose. Lower RMSD values indicate higher accuracy in pose prediction.

Table 6 presents the results of molecular docking studies conducted via AutoDock Vina software.⁶⁹ The five protein domains have been studied. Three of them are related to antibacterial activity (1KZN and 2Q85), one to anticancer (2H94), and the others (1EZF and 5VSZ) are related to antifungal activity.

2.12. 1EZF Protein Domain. Regarding antifungal activity, protein domain 1EZF reveals that the newly discovered ligands have affinities comparable to the native ligand's binding energy.

Table 6. Results— Binding Energies (Affinities) are Given in [kcal/mol] Unit

protein domain ID/ligand name	1EZf	1KZN	2H94	2Q85	5VSZ
native	−11.9	−9.1	−14.6	−10.9	−10.5
4	−5.7	−5.7	−6.2	−5.9	−5.9
5	−6.2	−5.2	−5.6	−5.7	−5.6
16	−11.4	−7.1	−9.5	−11.3	−11.3
17	−11.4	−8.3	−9.9	−12.7	−10.8
18	−11.1	−6.4	−9.6	−9.7	−10.6
19	−10.8	−8.0	−10.7	−11.3	−11.2
20	−10.9	−7.1	−9.9	−10.7	−10.6
21	−10.2	−8.0	−9.3	−11.6	−9.7
22	−11.3	−8.8	−10.2	−11.2	−11.9
23	−10.9	−7.6	−10.2	−9.5	−10.8
24	−10.4	−8.2	−9.3	−10.1	−10.1
25	−11.4	−8.7	−10.3	−11.6	−12.1
26	−11.6	−7.4	−10.0	−10.8	−11.3

Only in a few cases do the binding energies of new ligands deviate by more than 1 kcal/mol. Nevertheless, their affinities fall within the same range as the native ligand. The RMSD for the native ligand, in this case, is 1.30 Å (Table 5).⁸¹ Figure 5 shows how a protein and a molecule called a 26 ligand might bond together. They could form up to 11 hydrogen bonds, like tiny bridges holding them together. However, some of these bonds compete with each other, meaning only about six can form at the same time.

The 26 ligand can form hydrogen bonds with several specific amino acids in the 1EZf protein domain. These hydrogen bonds help hold the ligand and protein together. The shorter the distance between the atoms involved in a hydrogen bond, the stronger the bond. These hydrogen bonds involve the following atoms and distances:

- Ligand's keto-ester oxygen atom (acceptor) to LYS 117 A amine (donor): 2.15 Å

- Ligand's keto-ester oxygen atom (acceptor) to ARG 52 A amine (donor): 2.91 Å
- Ligand's 1,2,3-triazole nitrogen (acceptor) to ARG 77 A amine (donor): 1.97 Å (more likely) or 2.95 Å
- Ligand's other ester oxygen atom (acceptor) to ASN 215 A amine (donor): 2.71 or 2.78 Å
- Ligand's keto-ester oxygen atom (acceptor) to THR 214 A amine (donor): 2.94 Å
- Ligand's other 1,2,3-triazole nitrogen (acceptor) to ARG 218 A amine (donor): 2.15 or 2.43 Å
- Ligand's other 1,2,3-triazole nitrogen (acceptor) to THR 299 A amine (donor): 2.50 or 2.84 Å

2.13. 1KZN Protein Domain. These ligands exhibit similar or lower binding energies than the native ligand for the 1KZN protein domain. Specifically, ligands such as 17, 22, 24, and 25 demonstrate similar affinities (within ± 1 kcal/mol) to the native ligand, while others (4, 5, 16, 18, 19, 20, 21, 23 and 26) exhibit lower affinities. The reduced affinities of these ligands can be attributed to their larger sizes compared to the native ligand. Notably, the root-mean-square deviation (RMSD) between the initial pose of the native ligand and its reduced pose is 0.50 Å (Table 5), indicating an accurate recreation of the native ligand's binding configuration.⁸¹ Figure 6 shows how a protein and a molecule called a 25 ligand might bond together. They could form up to six hydrogen bonds, like tiny bridges holding them together. However, some of these bonds compete with each other, meaning only about four can form at the same time.

The 25 ligand can form hydrogen bonds with specific amino acids in the 1KZN protein domain. These hydrogen bonds involve the following atoms and distances:

- Ligand's keto-ester oxygen atom (acceptor) to ASN 46 A amine (donor): 2.83 Å
- Ligand's 1,2,3-triazole nitrogen (acceptor) to ARG 76 A amine (donor): 2.43 and 2.61 Å
- Ligand's ester oxygen atom (acceptor) to ARG 76 A amine (donor): 2.25, 2.26, and 2.45 Å

**Figure 5.** Potential hydrogen bonds between 26 ligand and the 1EZf protein domain.

Figure 6. Potential hydrogen bonds between ligand 2S and the 1KZN protein domain.

Figure 7. Potential hydrogen bonds between ligand 19 and the 2H94 protein domain.

2.14. 2H94 Protein Domain. For protein domain 2H94, the newly discovered ligands consistently exhibit significantly lower affinities than the native ligand. Despite this, their affinities are still noteworthy, suggesting potential anticancer activity. In this case, the RMSD for the initial pose recreation is 0.54 Å (Table 5), demonstrating faithful reproduction of the native ligand's pose.⁸¹ Figure 7 shows how a protein and a molecule called a 19 ligand might bond together. They could form up to six hydrogen bonds, like tiny bridges holding them together.

However, some of these bonds compete with each other, meaning only about five can form at the same time.

The 19 ligand can form hydrogen bonds with specific amino acids in the 2H94 protein domain. These hydrogen bonds involve the following atoms and distances:

- Ligand's keto-ester oxygen atom (acceptor) to ASN 535 A amine (donor): 2.74 Å
- Ligand's 1,2,3-triazole nitrogen (acceptor) to ASN 540 A amine (donor): 2.84 Å

Figure 8. Potential hydrogen bonds between ligand 17 and the 2Q85 protein domain.

Figure 9. Illustration of the fitting of the 17 ligand into the binding site of the 2Q85 protein domain.

- Ligand's keto-ester oxygen atom (acceptor) to HIS 564 A amine (donor): 2.65 Å
- Ligand's keto-ester oxygen atom (acceptor) to VAL 811 A amine (donor): 1.84 Å
- Ligand's keto-ester oxygen atom (acceptor) to THR 335 A amine (donor): 2.21 Å
- Ligand's keto-ester oxygen atom (acceptor) to HIS 812 A amine (donor): 2.57 Å

2.15. 2Q85 Protein Domain. In the case of protein domain 2Q85, some new ligands exhibit affinities similar to or even better than the initial ligand. Notably, the 17 ligand shows significantly higher affinity. However, most other ligands have lower affinities than the native ligand, indicating antibacterial activity. The RMSD for this domain is 1.54 Å (Table 5), indicating reasonable pose reproduction.⁸¹ Figure 8 shows how a protein and a molecule called a 17 ligand might bond together. They could form up to six hydrogen bonds, like tiny bridges

holding them together. However, some of these bonds compete with each other, meaning only about five can form at the same time. Figure 9 shows the same ligand bound to the 2Q85 protein domain similarly. The protein is shown as a surface instead of a ribbon, but the interactions remain the same.

The 17 ligand can form hydrogen bonds with specific amino acids in the 2Q85 protein domain. These hydrogen bonds involve the following atoms and distances:

- Ligand's keto-ester oxygen atom (acceptor) to ASN 233 A amine (donor): 2.26 Å
- Ligand's ether oxygen atom (acceptor) to LYS 262 A amine (donor): 2.23 Å
- Ligand's keto-ester oxygen atom (acceptor) to GLY 266 A amine (donor): 2.12 Å
- Ligand's uracil oxygen atom (acceptor) to ARG 214 A amine (donor): 2.08 and 2.39 Å

Figure 10. Native ligand, redocked ligand (sticks), and all new ligands at once are wired representations within the 2Q85 protein domain's active site.

Figure 11. Potential hydrogen bonds between ligand 22 and the SVSZ protein domain are shown in the figure. One hydrogen bond will likely be formed between the ligand's keto-ester oxygen atom (an acceptor) and the GLN 66 A residue of the domain. The length of this hydrogen bond is 2.56 Å.

- Ligand's uracil oxygen atom (acceptor) to SER 229 A hydroxyl group (donor): 2.60 Å

In this case, the hydrogen bonds between the ligand's keto-ester oxygen and ASN 233 A, ether oxygen and LYS 262 A, and

keto-ester oxygen and GLY 266 A are likely the strongest because they have the shortest distances.

Figure 10 shows all the different ligands docked into the 2Q85 protein domain. The docked ligands are shown as wireframe

Figure 12. Illustration of the fitting of the **22** ligand into the binding site of the SVSZ protein domain.

Figure 13. Native ligand, redocked ligand (sticks), and all new ligands at once are wired representations within the SVSZ protein domain's active site.

models, while the native ligand (the ligand that the protein naturally binds to) and the redocked ligand (a ligand that was docked back into the binding site) are shown as solid models.

The low RMSD (Root Mean Square Deviation) value indicates that the docked ligands occupy the same binding site as the native ligand. RMSD is a measure of how closely two structures match up. A lower RMSD value means that the structures are more similar.

In this case, the low RMSD value means that the docked ligands bind to the protein, similarly to the native ligand. This suggests that the docking procedure found the ligands' correct binding site.

2.16. 5V5Z Protein Domain. Finally, for protein domain 5V5Z, the new ligands exhibit similar or higher affinities than the native ligand, suggesting genuine antifungal activity. Notably, the energy-favorable pose (out of the top 10 poses) has been

chosen based on the lowest root-mean-square error (RMSE), which equals 1.65 Å (Table 5).⁸¹

Figure 11 shows the potential hydrogen bonds between the protein domain and the **22** ligand. There is the possibility of formation of at least one hydrogen bond. Figure 12 shows the same ligand in the binding site of the SVSZ protein domain but with the protein surface instead of the ribbon.

Figure 13 shows all the docked ligands (represented as wireframes) and the native and redocked ligands. The low value of RMSD (root-mean-square deviation) can be explained by the fact that all the ligands occupy the same binding site of the SVSZ protein domain.

All the ligands occupying the same binding site suggest competing for the same binding site. This could have implications for drug design, as it could be possible to design ligands that are more selective for the binding site and, therefore, have a higher affinity for the protein.

3. EXPERIMENTAL SECTION

3.1. Synthesis. **3.1.1. General Procedure for the Synthesis of Compounds (3–5).** Uracil (**1**) or 2-thiouracil (**2**) (11.9 mmol) was dissolved in 5 mL of anhydrous DMF, then K_2CO_3 was added and left for 30 min. The mixture was cooled to 0 °C, and propargyl bromide (26.2 mmol) was added. After 24 h of stirring, the reaction was stopped. DMF was evaporated, and the crude product obtained was dissolved in 10 mL of ethyl acetate. The organic layer was washed with brine (2 × 15 mL) and dried over anhydrous Na_2SO_4 . As an eluent, the crude compound was purified by column chromatography on silica gel using ethyl acetate/hexane (1.5:1). Two new compounds were isolated: **4** (323 mg, 26%) and **5** (443 mg, 34%).

3.1.2. General Procedure for the Synthesis of Compounds (16–26). The synthesis of azidoacetyl-substituted bile acids (**9–11**) or sterols (**14–15**) derivatives has been described previously.⁴⁶

An azidoacetate derivative of lithocholic acid (**9**) (201 mg, 0.426 mmol) or sterol (**14**) was dissolved in a *tert*-butanol/methanol mixture (5:1, 6 mL). A propargyl derivative of uracil (**3**) or 2-thiouracil (**4/5**) (40 mg, 0.213 mmol) was added at 65 °C (in a water bath). $CuSO_4 \cdot 5H_2O$ (3 mg, 3 mol %) and sodium ascorbate (9 mg, 20 mol %) in water (0.3 mL) were then added to the dissolved mixture. The mixture was heated to 60–65 °C in a water bath for 1 h. The resulting mixture was extracted with chloroform (10 mL), washed with brine (15 mL), and dried using anhydrous Na_2SO_4 . After evaporating the solvent and purifying the residue over silica gel ($CHCl_3/EtOAc$, 20:1), a total of 162 mg (72%) of the product (**16**) and 155 mg (65%) of the product (**25**) were obtained.

3.1.2.1. *N*(1),*N*(3)-Di(prop-2-yne-1-yl) Uracil (3**).** White solid (1120 mg, 63%). 1H NMR (400 MHz, $CDCl_3$): δ ppm 7.49 (d, J = 8.0 Hz, 1H, CH-5), 5.86 (d, J = 8.0 Hz, 1H, CH-6), 4.72 (ds, J = 2.5 Hz, 2H, N(3)CH₂-7'), 4.62 (ds, J = 2.6 Hz, 2H, N(1)CH₂-7), 2.52 (d, J = 2.6 Hz, 1H, CH-9), 2.19 (d, J = 2.5 Hz, 1H, CH-9'); ^{13}C { 1H } NMR (101 MHz, $CDCl_3$) δ 161.6 (C-4), 150.3 (C-2), 140.7 (C-6), 102.2 (C-5), 77.8 (C-8), 75.9 (C-8'), 75.8 (C-9), 70.4 (C-9'), 37.4 (C-7), 30.4 (C-7'); FT-IR (KBr, cm^{-1}) ν_{max} : 3303, 2306, 1717, 1676, 1275.

4. CONCLUSIONS

An effective synthesis, comprehensive spectroscopic characterization, and theoretical studies of the biological properties of 11 new steroid-pyrimidine bioconjugates connected with 1,2,3-triazole rings were carried out. The synthesis involved the strategic incorporation of triazole rings that linked steroid and pyrimidine units, which could offer synergistic effects in biological activity. Detailed spectroscopic and spectrometric analyses provided detailed structural information, confirming the successful formation of the bioconjugates. Additionally, the potential biological activities of the synthesized compounds were investigated in theoretical studies, such as molecular docking simulations. Computational methods provided insight into the molecular interactions between bioconjugates and target biological receptors. The combined experimental and theoretical approach confirmed the structural integrity of the synthesized compounds. It also provided valuable information about their potential biological activities, opening a promising avenue for further pharmaceutical development. Molecular docking studies predicted that the new ligands may have potential antibacterial and antifungal activities. Affinity energy for selected ligands is lower than the affinity energy of the native ligand toward *E. coli* MurB and against *C. albicans* fungi. This is a promising path for the development of new drugs, especially in the fight against infections resistant to currently available therapies. However, further experimental studies are required to confirm these predicted activities. In particular, *in vitro* and *in vivo* studies can provide valuable information on their efficacy and safety profile, enabling more informed decisions regarding drug development.

From squalamine to triazole ring derivatives: Exploring the versatility of steroidal bioconjugates

Anna Kawka, Hanna Koenig and Tomasz Pospieszny*

Department of Bioactive Products, Faculty of Chemistry, Adam Mickiewicz University Poznań, Poland

**Corresponding author: E-mail: tposp@amu.edu.pl.*

Introduction

In recent years, there has been a significant increase in interest in technologies for isolating, synthesizing, and modifying steroid conjugates. Compounds of natural origin have a broad spectrum of physicochemical, biological, and pharmacotherapeutic properties. Progress in the design of steroid derivatives with polyamines, polyalcohols, alkaloids, or nucleobases opens the way to obtaining highly effective drugs, carriers of biomolecules, organogelators, or complex compounds. Steroid structures are becoming increasingly important in pharmacology, biomimetics, supramolecular chemistry, and medicine [1,2].

Among all natural products, steroids form a large group of compounds showing significant and diverse biological activity [3]. Sterols (e.g., cholesterol, ergosterol, and stigmasterol) are part of the cell membrane of prokaryotes and eukaryotes (Fig. 8.1) [4]. Bile acids (e.g., lithocholic, deoxycholic, and cholic) as surfactants reduce surface tension and emulsify fats. In addition, they significantly affect the solubility of cholesterol contained in bile (Fig. 8.1) [5]. Hormones (e.g., estrogens, androgens, and gestagens) are responsible for gene expression, normal protein synthesis, and the basic regulatory and modification activities of target tissues (Fig. 8.1). In contrast, brassinosteroids (brassinolide) and withanolides (e.g., vitaferin A) are hormones of plant origin (Fig. 8.1). Their primary tasks include the proper course

FIGURE 8.1 Structures of selected steroids [3].

of the photosynthesis process, good plant growth, or the action of other phytohormones [6,7]. Withanolides also have immunosuppressive, anticancer, antiviral, and antibacterial properties [8]. In turn, vitamin D (ergocalciferol and cholecalciferol) are responsible for the proper calcium-phosphate metabolism and maintaining the functioning and structures of the skeletal system (Fig. 8.1) [9,10].

The essential structural element of all steroids is the cyclopentano[α]perhydrophenanthrene skeleton, formed of four condensed rings A, B, C, and D. The spatial arrangement of the rings, the type of substituents, the side chains of different lengths, and the degree of unsaturation determine the diversity of steroids. The connection of the condensed A/B rings in the skeleton of 1,2-cyclopentanoperhydrophenanthrene picks the *allo* series (as in *trans*-decaline) or normal steroids (as in *cis*-decaline) (Fig. 8.2). All natural steroids usually have *trans* stereochemistry of the B/C and C/D rings [11,12].

A significant group of steroids are bile acids. Their natural biosynthesis occurs in the liver, forming products of cholesterol metabolism (among others, oxidation of cholesterol by cytochrome P450) (Scheme 8.1). Then steroid acids combine with amino acids (glycine and taurine) and are stored as salts in

FIGURE 8.2 Atomic numbering and stereochemistry in steroid skeleton [11].

SCHEME 8.1 The part of multistep biosynthesis of bile acids [13].

the gallbladder. The resulting “primary bile acids” (glycocholic acid, taur-ocholic acid) undergo further modifications. Under intestinal bacteria’s influence, the amino acid molecule and hydroxyl group are detached at the 7 α carbon atom. This consequently leads to the preparation of deoxycholic and lithocholic acids [13,14].

All steroid acids are derived from 5 β -cholan-24-oic acid [15]. Compounds of this type are characterized by the presence of hydroxyl groups (3 α ; 3 α ,7 α ; 3 α ,12 α or 3 α ,7 α ,12 α) and a side chain with a carboxyl group at the C-17 atom [15,16]. Due to the rigid arrangement of alicyclic rings, curved skeleton, different reactivity of hydroxyl groups, and amphipathic properties, bile acids (lithocholic, deoxycholic, and cholic) have been used in the design of new macrocyclic compounds [17–19]. The biological activity of bile acids is mainly related to their spatial structure. Therefore, they are a precursor to preparing new substances with pharmacotherapeutic properties, used as drugs in treating liver and gastrointestinal tract disease [20–25]. In addition, their derivatives are known as receptors that detect molecules in solutions (e.g., biomarkers detecting organic anions or polypeptides) and can form inclusion complexes [26,27]. Bile acids play a significant role in supramolecular chemistry. Their derivatives are the primary material for synthesizing artificial molecular receptors susceptible to detecting foreign molecules in host cells [28,29].

Squalamine as steroid-polyamine conjugate with diverse biological activities

Control and regulation of life processes in organisms are usually carried out with the help of biogenic amines. These compounds are the main products of the decarboxylation of neutral and basic amino acids essential in the biological system; biogenic amines are often found as conjugates of fundamental neurohormones.

Squalamine (**10**) is one of the most essential natural steroid-polyamine conjugates (Fig. 8.3). It was first isolated from the liver cells of spiny dogfish (*Squalus acanthias*) [31]. This aminosterol antibiotic is a bioconjugate of spermidine and $7\alpha,24\text{-}\zeta$ -dihydroxy- 5α -cholestane 24-sulfate. It dissolves well in water thanks to a hydrophobic steroid skeleton, a polar hydroxyl group, and hydrophilic amino groups [31,32]. The specific stereochemistry and charge of squalamine allow it to penetrate the cell membrane. Thanks to this, it is possible to transport proteins associated with electrostatic interactions with the inner part of the cytoplasmic membrane. Squalamine prevents the development of Parkinson's disease by inhibiting the early aggregation of α -synuclein. It exhibits competitive effects against toxic proteins, separating α -synuclein from the membranes of synaptic vesicles responsible for the transport of neurotransmitters. Consequently, no harmful aggregates are formed, while previously formed sums become less toxic [33–36]. This compound has high biocidal activity against gram-positive, gram-negative, protozoa, fungi, and viruses (including HIV) [37–39]. In addition, squalamine slows the development of brain tumors by suppressing the growth of new blood vessels. Most

FIGURE 8.3 Squalamine and its molecular model [30].

importantly, squalamine intensifies the antitumor properties of cytotoxic agents against lung, breast, ovarian, and prostate cancers [40–46].

The antimicrobial activity of squalamine was compared with several natural peptide antibiotics, such as *Magainin-II*, CPF, and ampicillin. Table 8.1 presents the results of antimicrobial activity studies on squalamine conducted by Moore et al. [31] The activity of squalamine in inhibiting the development of candidiasis is two orders lower than for other compounds studied. The MIC value of this compound on *Candida albicans* (*C. albicans*) was 4–8 µg/mL. Most importantly, the antibiotic's action does not cause erythrocyte hemolysis [47].

Steroid-amino conjugates

Steroid-amino conjugates, often referred to as steroid-amino acid conjugates, are a class of molecules that combine a steroid skeleton with an amino acid moiety. These conjugates are a unique hybrid molecule that merges the biological activities of steroids and amino acids. The conjugation of steroids with amino acids can alter their properties, such as solubility and bioavailability, and may lead to distinct biological activities. Steroid-amino conjugates have been of interest in medicinal chemistry and drug development due to their potential to enhance the therapeutic effects or targeting of steroids while minimizing their side effects. These conjugates can also serve as valuable research tools to study the interactions between steroids and amino acids in biological systems.

Consequently, there are many reports in the chemical literature concerning the synthesis of squalamine and its derivatives [48–55]. The main criterion for the synthesis of biologically active steroid-polyamine conjugates is based on a rigid hydrophobic “tail” and an adjustable hydrophilic chain with a polar hydroxyl group constituting the “head” [56]. In turn, hydroxyl or carboxylate groups can easily remove or replace the current sulfate groups. However, only the steroid part is susceptible to modification [56].

Kim et al. synthesized an analog of squalamine from bisnoralcohol (**11**) (Scheme 8.2). The compound (**13**) showed significant activity against *M. luteus* 9341, *Staphylococcus aureus* (*S. aureus*) 6538P, *K. pneumoniae* 10031, *S. equi* 6580C, and *B. subtilis* 6633. However, it was inactive against *Escherichia coli* (*E. coli*) 25922, *P. aeruginosa* 27853, *P. mirabilis* 25933, *S. marcescens* 27117, and *S. typhimurium* 14028. It should be emphasized that the antibacterial activity of the compound (**13**) is lower than that of squalamine [57].

Shu et al. obtained squalamine derivatives with a side chain modified with an amino (**14**) or hydroxyl (**15**) group [58]. In contrast, stereoselective synthesis of new squalamine derivatives with transformations in the B ring led to compounds (**16**) and (**17**) [59]. It is worth noting that the above conjugates manifested similar biocidal properties to squalamine (Fig. 8.4).

TABLE 8.1 Antimicrobial activity of squalamine and other selected biologically active compounds [31].

Compound	Antimicrobial activity (MIC), µg/mL							
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)

SCHEME 8.2 Synthesis of a squalamine analog (**13**) [57].FIGURE 8.4 Synthetic derivatives of squalamine (**14**–**17**) [58,59].

The synthesis of many new squalamine derivatives distinguished by significant biological activity was developed by Kim et al. Their study included the effect of stereochemistry at the C(3)/C(5) position of the steroid ring on the lethality of pathogens. The type of polyamine attached to the steroid A ring's C(3) position was also important. The obtained conjugates showed antiseptic solid activity. All 3 α (or β)-aminosteroids were characterized by considerable in vitro activity against gram-positive bacteria. Notably, compound (**25**) with a configuration of 3 β , 5 β and a polyamine chain containing four ammonium groups at the C(3) position of the steroid A ring showed the most muscular toxicity against *S. aureus* ATCC25923P, *M. luteus* ATCC9341, and *B. subtilis* ATCC6633. The highest biocidal activity against *S. aureus* ATCC25923P was demonstrated by the compound (**18**) among the 3 α , 5 α configurations. Conjugates (**20**, **24**) with a 3 α , 5 β configuration had less antibacterial activity (Fig. 8.5) [60].

Several new synthetic derivatives of squalamine were presented by Brunel and Letourneux [61,62]. Similarly, the biological activity of conjugates is determined by the stereochemistry of sterols and the chain length of the attached polyamine (spermine or spermidine) to the C(3) position of the steroid skeleton. A stereoisomer with a 3 β configuration exhibits much better biocidal properties than a 3 α compound (Fig. 8.6).

FIGURE 8.5 Synthetic steroid-polyamine conjugates (18–28) [60].

FIGURE 8.6 Analogs of squalamine (29–34) [61,62].

Rao et al. described novel squalamine derivatives isolated from dogfish liver cells (Fig. 8.7) [63]. Their content in liver cells was much lower (20–100 mg) than the concentration of squalamine (400–800 mg). Still, their antibacterial activity was equally interesting. The structure of all conjugates (35–41) was determined using spectral methods (2D NMR, HR FAB-MS).

Table 8.2 presents the activity of isolated aminosterols and squalamine against selected microbial species. The lowest aseptic activity was shown by

conjugate (**39**). The compounds (**35**, **40**) showed weak activity against *E. coli* and *P. aeruginosa*.

A series of analogs (**43–52**) of the MSI-1436 conjugate has been characterized by Shu et al. [58]. The multistep (9–13 steps) and compelling synthesis of compounds confirmed the critical influence of stereochemistry at the C(3) and C(7) positions on their biological activity. Notably, the change in stereochemistry at the carbon atom C(24) of the side chain had a negligible effect on bioactivity (Fig. 8.8).

Conjugates of steroid-polyamine with antimicrobial activities

Innovative methods enable the efficient synthesis of steroid conjugates with different pharmacological activities. The conjugation reaction of cholesteryl

FIGURE 8.8 Structure of MSI-1436 (42) and its analogs (43–52) [58].

ester (53) and 5'-azido-5'-deoxythymidine (54) using “click” chemistry allows obtaining compounds that enhance the uptake of oligonucleotides by the cell (Scheme 8.3). In addition, as carriers, they transmit them inside the cell. Instead, conjugates (55, 56) effectively inhibit hepatitis C [64,65].

It is worth noting that steroid-polyamine conjugates are also used in other fields of medicine than combating microorganisms. In vitro and in vivo studies have shown that Genzyme GL-67 (57) and bis(guanidine)tren-cholesterol (58) are highly effective in gene transfection (Fig. 8.9) [66,67].

Golebiewski et al. described using cosalane (59) as a highly effective agent against HIV-1 and HIV-2 [68–70]. Cell membranes can be chemically altered to facilitate the uptake of macromolecules. Peterson's research group obtained a conjugate (60), allowing antibody uptake and forming protein complexes bound in mammalian cells [70]. They also effectively synthesized

SCHEME 8.3 Synthesis of conjugates (55) and (56) inhibiting the development of HCV [64,65].

FIGURE 8.9 Spermidine and guanidine-cholesterol conjugates [66,67].

FIGURE 8.10 Steroid conjugates with different biological activity [68].

7 α -substituted, cholesterol-modified derivatives of β -estradiol (**61**) and (**62**) (Fig. 8.10). These compounds showed a significant affinity for estrogen receptors [71,72].

Degteva et al. designed the synthesis of *p*-[*N,N*-bis-(2-chloroethyl)amino] phenylacetate 3 β -hydroxy-5-cholestane (**63**), which was characterized by vigorous antitumor activity [73]. In turn, the compound (**64**) described by Ji et al. selectively delivers boron atoms to cancer cells [74]. Wall et al. synthesized a conjugate (**65**) that showed high activity against various tumors and leukemia (Fig. 8.11) [75].

Synthesis of steroid's organogels

Conjugate (**66**) was also effectively obtained, the structure of which is similar to cationic surfactants commonly used in the polycondensation reaction (Fig. 8.12). This compound exhibited significant gelling properties [76].

In turn, Ono, Jung, et al. designed the synthesis of a gelator (**67**) made of cholesterol structure and corona ether moiety [77–79]. This compound

FIGURE 8.11 Biologically active steroid conjugates [73–75].

FIGURE 8.12 Steroid conjugate with gelling properties [76].

showed good selectivity toward the binding of potassium ions. It did not form complexes with lithium, sodium, rubidium, or cesium ions. Another conjugate (**68**) containing corona ether aza was used as a template for the polycondensation reaction sol-gel (Fig. 8.13). Importantly, it formed only in the presence of metals, and in their absence, it assumed a granular structure [80].

Studies on the structure and biological properties of squalamine and its analogs provided data on the formation of new compounds with pharmacological potential. Compounds of this type should be characterized by a giant, rigid hydrophobic skeleton that is easily modified and a polar hydrophilic chain. The structure of polyamine is not essential. In contrast, the sulfone group can be easily replaced by another group (carboxyl or hydroxyl) or removed. The stereochemistry of the polyamine chain at the C(3), C(5), and C(7) positions of the steroid has a crucial influence on biological activity (Fig. 8.14). Many literature papers have analyzed the strong biocidal properties of squalamine and its derivatives [56,81,82].

FIGURE 8.13 Steroid conjugates exhibit selective reactivity to cations [77–80].

FIGURE 8.14 Selected structures with group modification.

Bile acid conjugates by the “click” chemistry method

The “click” chemistry is a relatively new and desirable method of modern organic synthesis. The products of this reaction are stable in solvents of different polarities (e.g., in water) and resistant to oxidation, reduction, or metabolic degradation. In addition, 1,2,3-triazole rings are very often involved in forming hydrogen bonds. As a consequence, the durability of the tested system increases. Crucial is the method using catalytic amounts of Cu(I) in 1,3-dipolar cycloaddition, also called the Huisgen reaction (Scheme 8.4). This straightforward way of synthesizing 1,2,3-triazole rings uses terminal alkynes

SCHEME 8.4 The reaction of formation of 1,4- and/or 1,5-disubstituted 1,2,3-triazole [87].

and azides as reactants [83,84]. The Huisgen reaction's use in forming macromolecular bile acid derivatives is exceptionally functional [85,86].

A rigid skeleton, high activity of polar hydroxyl and carboxyl groups, and amphipathic characteristics distinguish bile acids. Several valuable properties determine their massive impact on the pharmaceutical industry. Steroid acids are an excellent biological material used to synthesize macrocyclic compounds (e.g., molecular pincers), elements of the structure of organisms, or fluconazole derivatives [88–91].

Fluconazole (**69**) is a potent medicinal substance with antifungal and antimicrobial properties (Fig. 8.15). It consists of a triazole ring bound to fluorinated benzene and contains a hydroxide group. Due to the increasing drug resistance of bacteria and the decrease in its effectiveness, it was necessary to modify the structure of fluconazole. The synthesis of new fluconazole derivatives was performed using the amphiphilic properties of bile acids. A conjugate of deoxycholic acid (**71,73**) and cholic acid (**72,74**) was obtained, connected with a 1,2,3-triazole ring to a drug molecule (Fig. 8.16). According to the assumption, the bile acid unit acts as a carrier of the drug substance. At the same time, fluconazole is an inhibitor of the enzymes of the relevant bacterial strains. The new structure has gained many benefits from the possibility of hydrogen bond formation. However, from a biological perspective, exceptional resistance to metabolic degradation was an additional

FIGURE 8.15 Fluconazole (**69**) and its alkyne derivative (**70**) [88].

FIGURE 8.16 Bile acid and fluconazole conjugate with antifungal properties [90–92].

attribute. Most importantly, the biocidal compounds obtained showed almost 100% lethality against microorganisms belonging to *Candida* strains, such as *C. parapsilosis*, *C. albicans*, and *Sporothrix schenckii* [90–92]. The novel bioconjugates (71–74) exhibited antifungal activity in the MIC range of 3.12–6.25 mg/mL [90]. In contrast, a molecule of imidazole/benzimidazole (75/76) or triazole/benzotriazole (77/78) attached in the C-24 position of bile acid showed slight antifungal activity (Fig. 8.16).

Bile acids-purine with antiparasitic activity

Corrales et al. obtained new cholic acid and 6-thiopurine derivatives linked by a 1,2,3-triazole system [93]. Based on in vivo studies, compounds with higher antimalarial activity than chloroquine were evaluated (79–82). In vitro evaluation confirmed the excellent training of the compound (83) against Leishman's parasite (Fig. 8.17). Notably, the synthesized derivatives are nontoxic to the mammal's cells. The lack of cytotoxicity was most likely due to intracellular biochemical or metabolic differences in parasite-host cells [94]. From an anatomical perspective, mammalian cells are enriched with drug outflow pumps, thanks to which it is possible to transport lipophilic nucleoside analogs

FIGURE 8.17 Steroid-thiopurine conjugates with antiparasitic activity [93–95].

outside the cell. That is why thiopurine-steroid conjugates are distinguished by considerable activity against malaria or antileishmanial. In turn, derivatives of 1,2,3-triazoles (**79**, **81**, **82**) were also obtained by 1,3-dipolar cycloaddition of final alkynes to the azide group in a molecule of acetic acid or cholic acid in the presence of Cu(I) and DMSO [95]. The condensation compound (**83**) showed antimalarial activity similar to chloroquine at the same dose on days 7 and 9. In contrast, after 12 days, all the new bioconjugates showed more excellent biocidal activity than chloroquine [96].

Antinarelli et al. obtained amino choline-steroid conjugates with considerable activity against the Leishman parasite and *Mycobacterium tuberculosis* (*M. tuberculosis*) than similar intermediate alkyne structures. An excellent percentage of inhibition against *M. tuberculosis* (MIC = 8.8 μ M) was obtained for the compound (**84**), which can be compared with the activity of popular *antituberculosis* drugs. In addition, all new conjugates (**85–87**) exhibited potent toxicity to *promastigote* and *amastigota L. major*, leishmanicidal, and antituberculosis effects, indicating the great potential of steroids as drug carriers (Scheme 8.5) [97].

Synthesis of bile acids-nucleosides derivatives with 1,2,3-triazole rings

Efficient synthesis of new bile acid conjugates and nucleosides connected by a 1,2,3-triazole ring was also carried out (Scheme 8.6). Based on in vitro

SCHEME 8.5 Synthesis of amino choline and cholic acid conjugates [97].

SCHEME 8.6 Synthesis of steroid-uridine triazole derivatives [98].

metabolism, their antitumor activity against three cancer cell lines, PC-3, MCF-7, and IMR-32, and antimycobacterial activity against *M. tuberculosis* H37Rv (ATCC strain 27294) were estimated.

The highest activity against MCF-7 and IMR-32 (ICP = 8.084 and 8.71 μM , respectively) was shown by the compounds cholic acid-uridine-triazole (**91**) and cholic acid-uridine-triazole linked by the phenylalanine moiety (**89**). In contrast, the conjugate deoxycholic acid-adenosine triazole (**92**) was distinguished by the best antituberculosis properties (MIC = 4.09 μM). The new products (**88–95**) showed no toxicity to the average human embryonic kidney cell line (HEK 293 T) (Fig. 8.18). In vitro evaluation confirmed their significant antitumor and antituberculous potential [98].

FIGURE 8.18 Conjugates bile acid-nucleoside containing 1,2,3-triazole rings [98].

Synthesis of macrocycles with 1,2,3-triazole rings

Steroids are made of rigid chiral tetras of the acyclic core. Due to curved structures, amphiphilicity, and unequal polarity, hydrophilic and hydrophobic ends can form self-assembling micelles (Fig. 8.19). Modifying hydroxyl or carboxyl groups through esterification, etherification, oxidation, or reduction strives to design new structures with a wide range of applications. Pharmacological conjugates, chemical sensors, biosensors, drug precursors, and molecular carriers are particularly important [99].

Chemoselective 1,3-dipolar azide-alkyne cycloaddition (CuAAC) is an attractive building block for joining to synthesize macrocyclic structures such as clusters, dendrimers, polymers, or polypeptides. In addition, the chemical inertness of the triazole ring significantly affects their physicochemical properties, such as blocking parts of the molecule, polarity, or susceptibility to interaction with the “guest.”

Khaligh et al. synthesized menthol conjugation with bile acids using “click” chemistry. Methylated menthol was reacted with sodium azide in DMF, while efficient esterification of bile acid with propargyl bromide in the presence of potassium carbonate gave a second reactant to form 1,2,3-triazole.

FIGURE 8.19 Bile acids form micelles.

The conjugates obtained by the “click” reaction (**96–98**) were evaluated for biological activity (Scheme 8.7). In vitro studies have shown that their antibacterial activity against *Enterococcus faecium* is higher ($\text{MIC} < 10 \mu\text{M}$) than for menthol ($\text{MIC} = 410 \mu\text{M}$), free bile acids ($\text{MIC} = 10, 20, 157, 410 \mu\text{M}$), and even the strong antibiotic cefixime ($\text{MIC} = 35410 \mu\text{M}$) [100].

The “click” chemistry method was also used to obtain dimers of deoxycholic acid derivatives (Scheme 8.8) [101]. The introduction of the azide group took place successively by securing hydroxyl groups (**99**), reducing the carboxyl group, and reacting nucleophilic $\text{S}_{\text{N}}2$ with sodium azide (**100**). In contrast, the propargyl ester (**101**) was formed under the Mitsunobu reaction conditions. The steroid dimer (**102**) was subjected to calculations (PM3, CaChe Fujitsu). It was found that the conformer in orientation was more energy stable than the *anticonformer* in direction.

Anandkumar et al. synthesized steroidal “molecular pocket” type dendrimers with excellent anticancer activity (Scheme 8.9) [102]. First-generation chlorodendrimers were formed by a “click” reaction from 1,3,5-tris(aminomethyl)arene and 3,1 equivalent to 1,3-bis(chloromethyl)-5-(propargyl oxy)-benzene. Subsequently, it was converted into suitable

SCHEME 8.7 Bile acid and menthol bioconjugate preparation (**96–98**) [100].SCHEME 8.8 Synthesis of steroid dimer (**102**) [101].

azidodendrimers, and during the next “click” reaction, second-generation azidodendrimers were obtained. In contrast, the corresponding bile acids (cholic/deoxycholic) were modified by reaction with propargyl bromide and *p*-TsOH and acylated to safeguard the alkyne group. The design performance of the steroid platforms was best for zero-generation dendrimers and lowest for second-generation dendrimers. The MTT assessment of activity against C6 glioma cancer cells confirmed the highest efficacy for second-generation compounds (**107**, **108**), with an IC₅₀ value of 10.48 μM .

Conjugates bile acids-triazole as ligands

Another type of macrocyclic compound susceptible to anion binding is cholophanes (Scheme 8.10). The 3 α -OH group of the deoxycholic acid derivative was

SCHEME 8.9 Synthesis of steroidal dendrimers [102].

SCHEME 8.10 Synthesis of cholophane (**111**, **112**) and exemplary interaction with chloride anion (**113**) [103,104].

modified in the presence of propargyl bromide, NaH in THF, and then acylated with bromoacetyl bromide with the addition of potassium carbonate in chloroform. The resulting monoester (**109**) was then converted to an azide derivative (**110**), after which a cholophane (**111**) was formed in a “click” reaction with good efficiency. Due to the more efficient formation of hydrogen bonds by alkyl-1,2,3-triazole (**112**), methylation with methyl iodide and the exchange of anions were performed. To analyze the donor properties of cholophane, titration with Bu₄N⁺X[−] salts in CDCl₃ was carried out and controlled by NMR. On the spectrum, a change in the shift of signals from protons in the triazole ring and acetylmethylene was observed, which resulted from interaction with the anion. In addition, association constants were estimated according to the order Cl[−] > H₂SO₄[−] > F[−] > Br[−] > CH₃COO[−] > H₂PO₄^{2−}. A higher affinity for chloride ion binding (K_a = 3700 M^{−1}) may result from the most stable binding to hydrogen [103,104].

Li et al. synthesized a steroid dimer with a similar structure [105,106]. The side chain of bile acid was coupled to the hydroxyl group at the C-3 α position (Scheme 8.11). The spectroscopic analysis of ¹H NMR excluded the participation of protons from hydroxyl groups in anion binding. In contrast, the new

SCHEME 8.11 Synthesis of a head-to-tail steroid dimer [105,106].

conjugate steroid-triazole (**115a**, **115b**) was the most highly selective for fluoride ions. The calculated constants of K_1 and K_2 were $560 (\pm 8)$ and $18 (\pm 3) \text{ M}^{-1}$, respectively. TBAF appendix (2 eq.) caused the signal loss from the aliphatic proton while strengthening two hydrogen bonds in the dimer structure (**116a**, **116b**).

Nayal et al. have described cholapods containing units with colorimetric properties [107]. The highly efficient reaction under click chemistry (efficiency > 80%) allowed for the effective binding of selected anions (Scheme 8.12). For compound (**120a**), after adding $\text{Bu}_4\text{N}^+\text{H}_2\text{PO}_4^-$ (in CHCl_3), its color changed to yellow, while the UV absorption band at 360 nm was reduced and shifted to 400 nm. The second compound (**120b**) showed a similar decrease at 380 nm and an increase at 600 nm while turning blue in the presence of TBAF, $\text{BuNCH}_3\text{CO}_2$ (in $\text{Bu}_4\text{N}^+\text{H}_2\text{PO}_4^-$). Cholapods (**120a**, **120b**) were characterized by increased selectivity for H_2PO_4^- ions (**121a**, **121b**) than for Cl^- ions. This is a significant difference compared to macrocyclic compounds.

The “click” chemistry allowed the design of new functionalized hybrids of bile acids and calixarene [108]. The synthesis of these triazole conjugates consisted again of the conjugation of a steroid triazide (**118**) and calixarene, previously enriched with a propargyl group (**123**) (Scheme 8.13). The resulting compound (**124**) showed two absorption peaks derived from the triazole and

SCHEME 8.12 Synthesis of cholapods [107].

SCHEME 8.13 Synthesis of bile acid-calixarene hybrids (**124**) [108].

calixarene rings at 284 and 289 nm, respectively. The peaks were suppressed in the presence of selected metal perchlorates in CH₃CN. Two isometric points were observed at wavelengths of 276 and 302 nm. The hybrid receptor's binding analysis showed the highest mercury affinity ($K_a = 1.2 \times 10^4 \text{ M}^{-1}$). The critical power of other metal ions was as follows: $\text{Hg}^{2+} > \text{Cd}^{2+} > \text{Zn}^{2+} > \text{Pb}^{2+} > \text{Li}^+ > \text{Mn}^{2+} > \text{Cu}^{2+}$.

Synthesis of other derivatives of bile acids with 1,2,3-triazole rings

Another compound type is bile acid-sterol dimers (**135–140**) connected by a 1,2,3-triazole ring (Scheme 8.14). Corresponding azido acetoxy substituted bile acid derivatives and propionyl sterol derivatives were reacted by adding Cu(I) ions. The newly obtained products were confirmed by spectroscopic analysis and mass spectrometry. In silico studies conducted by the PASS method indicated their outstanding biological activity (Table 8.3) [109].

FIGURE 8.21 Conjugate cholic acid β -lactam [111].

Another example of using bile acid molecules in combination with a 1,2,3-triazole ring is a model leading to the formation of polymers (Fig. 8.20). These products make it possible to maintain the stabilization of silver nanoparticles, which have been used in a modern approach to the selective recognition of iodide anions by colorimetric methods [110].

S. Vatmurge et al. designed the synthesis of steroid conjugates with β -lactams linked to 1,2,3-triazole rings (Fig. 8.21) [111]. This was due to the newly emerging strains of pathogens showing high drug resistance to medicinal substances containing β -lactam groups. In the era of the development of pharmaceuticals and medicine and the appearance of yet-unidentified pathogenic microorganisms, there is a great need to synthesize effective compounds with antimicrobial properties. The conjugates obtained by Vatmurge were characterized by high pharmacotherapeutic potential against the following strains: *C. albicans*, *Cryptococcus neoformans*, *Yarrowia lipolytica*, *Fusarium oxysporum*, *Benjaminiellapoitrasii*, and bacteria of the following types: *E. coli* and *S. aureus*.

The new quasi-podands containing 1,2,3-triazole rings were synthesized by Pospieszny et al. (Scheme 8.15). A “click” reaction between the corresponding propargylic esters of bile derivatives (145–147) and 1,3,5-tris(azidomethyl) benzene resulted in conjugates (148–150) having a rigid benzyl platform with high efficiency (>85%) [87]. The structure with an aromatic ring promotes the formation of conformers that can interact with the surface of biopolymers as anchors.

SCHEME 8.15 Synthesis of quasi-podands of method “click” chemistry [87].

Based on excellent physicochemical properties, the synthesis of three new bile acid dimers connected by 1,2,3-triazole rings (**151–153**) and two dimers substituted in the C-3 position with bromoacetoxy groups (**154,155**) was designed (Fig. 8.22) [112]. Complete spectroscopic analysis (1H NMR,

FIGURE 8.22 Synthesis of bile acid dimers containing 1,2,3-triazole systems [112].

^{13}C NMR) and mass spectrometry (ESI-MS, MALDI) confirmed their structure, and their molecular models were determined using the semiempirical PM5 method.

Subsequently, the obtained conjugates were used as ligands to synthesize adducts with phthalic, terephthalic, and 4-aminobenzoic acid (PABA, vitamin B₁₀). Studies have shown that adducts are formed due to the formation of hydrogen bonds between the hydroxyl groups of the steroid skeleton and the carboxyl groups of added aromatic acids. Fig. 8.23 shows the spectrum of ^1H NMR of the conjugate (**153**) and its adducts with phthalic, terephthalic, and 4-aminobenzoic acids. A characteristic feature

FIGURE 8.23 ^1H NMR in 4.5–3.0 ppm region of dimers (**153**) and its adducts with phthalic acid, terephthalic and PABA in DMSO- d_6 [112].

appearing in the ^1H NMR spectra of the corresponding adducts is the presence of extended $3\beta\text{-H}$ and $12\beta\text{-H}$ proton signals and expanded and flattened signals coming from protons of $3\alpha\text{-OH}$ and $12\alpha\text{-OH}$ groups. In the ^1H NMR spectrum of the dimer adduct (**153**) with phthalic acid, it can be seen that the signals coming from the protons of the $7\alpha\text{-OH}$ and $12\alpha\text{-OH}$ groups have been significantly flattened, and the signal coming from the proton of the $3\alpha\text{-OH}$ group disappears. This is related to these groups' participation in forming intermolecular hydrogen bonds, which is also facilitated by the location of carboxyl groups in the phthalic acid molecule in the ortho position. The presence of blocking groups at the C(3) position of the steroid skeleton in conjugates (**154**) and (**155**) prevents the formation of hydrogen bonds between conjugates and aromatic acids and the construction of adducts. It follows that only hydroxyl groups participate in forming hydrogen bonds, while nitrogen atoms of the triazole ring do not.

Conclusions

The synthesis of new steroid conjugates and the application of click chemistry are essential for developing science for several vital reasons. Firstly, by creating novel steroid conjugates, scientists can fine-tune the properties of steroids, making them more effective for therapeutic purposes. This can lead to the development of new and improved drugs with enhanced efficacy and reduced side effects. Secondly, steroid conjugates can be used to investigate the complex interactions between steroids and other biomolecules in biological systems. This helps researchers gain a deeper understanding of physiological processes and disease pathways. Whereas “click” chemistry, a highly efficient and selective chemical reaction, facilitates the precise conjugation of molecules. Its use in steroid conjugate synthesis enables the creation of complex molecules with high precision, offering new possibilities for drug design and biomaterial development. Steroid conjugates can target specific tissues or cells, allowing for more targeted therapies. This can reduce off-target effects and improve treatments' overall safety and efficacy. The versatility of steroid conjugates and click chemistry extends beyond drug development to materials science, diagnostics, and biotechnology. This broadens the impact of these research areas across various scientific disciplines. The synthesis of new steroid conjugates and the application of click chemistry are pivotal in advancing scientific knowledge and innovation. They contribute to the development of better drugs, an improved understanding of biological processes, and the creation of innovative materials and technologies, ultimately benefiting both scientific research and society.

Supporting Information

ABSTRACT: An innovative approach to producing derivatives of bile acids has been devised, utilizing the principles of “click” chemistry. By employing intermolecular [3 + 2] cycloaddition between the newly developed acyl propiolic esters of bile acids and the azide groups of 1,3,5-tris(azidomethyl)benzene, a novel class of quasi-podands featuring 1,2,3-triazole rings has been synthesized. Identifying and characterizing these six compounds involved comprehensive analysis through spectral techniques (^1H NMR, ^{13}C NMR, and FT-IR), mass spectrometry, and the PMS semiempirical method. The synthesized compounds’ pharmacotherapeutic potential has been evaluated, employing the Prediction of Activity Spectra for Substances (PASS) methodology. Additionally, molecular docking was performed for all molecules.

1. INTRODUCTION

“Click” chemistry is one of the most modern paths of design and synthesis of new compounds that can be used in medicine, pharmacology, biotechnology, or supramolecular chemistry. Sharpless optimized this innovative method’s conditions for synthesizing new compounds used primarily as drugs.^{1,2}

Obtaining new conjugates by “click” chemistry covers a broad spectrum of reactions leading to forming a carbon-heteroatom bond. Most importantly, it is characterized by extraordinary efficiency, selectivity, simple reaction conditions, and easy product isolation. Moreover, the product is stable in many solvents (e.g., in water).^{3–5}

[3 + 2] Cycloaddition catalyzed by copper(I) is a representative example of a reaction based on “click” chemistry conditions (Scheme 1). The Huisgen reaction between azides and terminal alkynes is considered the primary method for synthesizing 1,2,3-triazoles, characterized by antimicrobial and antitumor properties. In biological systems, these compounds show high resistance to hydrolysis, oxidation, reduction, or metabolic degradation reactions. In addition, they can interact with biological molecules by forming hydrogen bonds or dipole–dipole interactions. Moreover, the bonds that are formed are resistant to cleavage even by proteases. The result may be triazole systems peptide bond analogues.^{6,7} Literature data show that these are 1,2,3-triazole compounds characterized by unique pharmacotherapeutic effects, especially antihypertensive, antimalarial, antioxidant, antidepressant, antimicrobial, anti-inflammatory, and anticancer effects.^{8–15} The “click” method was used to obtain new steroid conjugates containing 1,2,3-triazole rings.

Compounds of natural origin affect the proper functioning of all cells in living organisms. Bile acids as representatives of steroids are responsible for the digestion and absorption of lipids in the small intestine, the right amount of cholesterol, glucose metabolism, or the composition of the intestinal microbiota. Their biosynthesis begins in liver cells by the oxidation of cholesterol by cytochrome P450, and the final products are stored in the form of conjugated bile salts with the amino acids glycine and taurine. Bile acids (lithocholic acid, deoxycholic acid, and cholic acid) are distinguished by a large, curved steroid skeleton, A/B rings in *cis* geometry, enantiomeric purity, a long chain attached to the C(17) atom with a carboxyl group, amphipathic and polar hydroxyl groups with different chemical reactivity ($3\alpha\text{-OH} > 7\alpha\text{-OH} > 12\alpha\text{-OH}$).^{16–18} Their derivatives are valuable and essential for synthesizing macrocyclic compounds, steroid dimers, cholophanes, and drug-transporting molecules. Also, they can be used in designing molecular receptors capable of guest recognition in guest–host chemistry. Steroid conjugates have been used in medicine, pharmacology, supramolecular chemistry, biotechnology, and biomimetics.^{19–22}

The growing interest in macromolecular derivatives of bile acids led to the development of the synthesis and use of molecular pockets^{23–25} and umbrellas.^{26–28} These compounds

comprise at least two amphiphilic parts connected by a labile chain to the central atom. On the other hand, quasi-podands have a rigid benzene “platform” that allows them to obtain a conformer with appropriate geometry. Also, it can be crucial during interaction with the surface of biopolymers or acting as an “anchor” in biological systems.^{29,30} Such systems have found application as carriers of biological molecules, hydrogelators, organogelators, or artificial receptors.^{31–37}

The combination of beneficial physicochemical properties of bile acids, triazole systems, and the aromatic ring may lead to the preparation of new quasi-podands with great application potential. It is worth noting that podands are simple analogues of crown ethers and cryptands; thus, they can be valuable ligands in forming stable complexes with monovalent cations.^{38,39} In addition, synthetic podands are easy to synthesize (as opposed to biological ones), and the spectrum of modification of their structures is endless.

2. RESULTS AND DISCUSSION

2.1. Synthesis. This study presents the synthesis and characterization of novel quasi-podands that are connected with a 1,2,3-triazole ring derived from propionic esters of bile acids and 1,3,5-tris(azidomethyl)benzene. The propionic esters of bile acids and 1,3,5-tris(azidomethyl)benzene were synthesized using previously established methods as described in Scheme 2.

The synthetic procedures for compounds 9–12 are presented in Scheme 3. Our experiments yielded trisubstituted products 10–12 as well as one disubstituted product 9, which were isolated and characterized. Unlike molecular pocket or umbrella structures, these conjugates possess a rigid benzyl platform. This structural feature facilitates the formation of conformers with favorable geometries. The flat aromatic ring enables effective interactions with various surfaces, including biopolymers, making it function as a specific anchor. Previous research by Ghosh et al. has described similar connections achieved using cholesterol derivatives. Interestingly, these compounds exhibit

Scheme 3. "Click" Synthesis of Quasi-Podands of Bile Acids Derivatives Linked by 1,2,3-Triazole Ring (9–12)

distinct gelling properties and detected ions Cu²⁺, Ag⁺, and Hg²⁺.⁴⁰

2.2. Spectroscopic Characteristic. The structural characterization of all synthesized compounds was accomplished through analysis of their ¹H and ¹³C NMR, FT-IR, and ESI-MS spectra. In addition, PM5 calculations were conducted for each compound to further explore their properties and characteristics.^{41–43}

The ¹H NMR spectra of compounds **9** and **10–12** exhibit distinctive patterns of signals. Notably, in the range of 5.07–4.81 ppm, characteristic multiplets are observed, which can be attributed to the C3β-H protons of the steroid skeleton. Additionally, two hydrogen singlets appear in the ranges of 0.73–0.64 and 0.95–0.94 ppm, accompanied by characteristic doublets at 0.92–0.81 ppm, assigned to CH₃-18, CH₃-19, and CH₃-21, respectively. In the spectra of compounds **11** and **12**, there are characteristic broad singlets observed in the range of 5.09–5.07 ppm, corresponding to the C12β-H protons. Furthermore, singlet in the range of 4.94–4.81 ppm is observed for the C7β-H protons in compound **12**. A distinctive signal at 4.37 ppm is observed in the ¹H NMR spectra of compound **9**, which can be attributed to the protons of the –CH₂–N₃ group. This signal serves as a diagnostic marker and is absent in the spectra of compounds **10–12**. The singlet at 5.55 ppm represents the signal for the two methylene protons of the Ph–CH₂–triazole ring group (refer to Figure 1).

Additionally, in the ¹H NMR spectrum of compound **9**, there is a distinctive and diagnostically significant singlet observed at 8.06 ppm, which can be attributed to the two protons of the triazole rings. Conversely, in the spectra of compounds **11–12**, three protons of the triazole rings are observed in the range of 8.10–8.06 ppm. Moreover, the ¹H NMR spectra of compounds **9–12** exhibit characteristic signals for the aromatic protons of the 1,3,5-trisubstituted benzene. These signals appear as singlets at 7.22–7.19 ppm for compound **9** and at 7.21–7.19 ppm for compounds **10–12**. These signals serve as prominent markers in the spectra of these compounds.

The ¹³C NMR spectra of compounds **9–12** exhibit distinct peaks at the following chemical shifts: 12.4–12.0, 23.4–22.8, and 18.2–17.4 ppm, which correspond to CH₃-18, CH₃-19, and CH₃-21, respectively. However, the carbon atoms located in the 3α positions of the formyloxy groups exhibit resonance at 160.1–160.0 ppm. The carbon atoms within the C(12)=O steroid skeleton generate signals at 170.7 ppm, whereas the carbon atoms of C(7)=O are detected at 170.8 ppm. Alternatively, the carbon atoms of the C(24)=O group produce signals in the range of 174.8–174.5 ppm. The diagnostic signal for carbon atoms in the 1,2,3-triazole rings of compounds **9–12** is observed between 143.3–141.4 and 128.0–127.5 ppm, respectively. The carbon atoms within the CO₂–CH₂–triazole ring unit resonate within the range of 53.8–53.4 ppm (CH₂). In the ¹³C NMR spectrum of compound **9**, the signal arising from the CH₂ group in the N₃–CH₂–Ph moiety is observed at 53.7 ppm. The spectra of compounds **10–12** display signals associated with the CH₂ atoms in the triazole ring–CH₂–Ph structure.

The FT-IR spectra of compounds **5** and **6** exhibit notable features. These include bands at 3251, 3292, and 3286 cm^{–1}, which are attributed to the stretching vibrations of the ν(≡C–H) group. The stretching vibrations of C–H bonds, forming a conjugate structure, merge into a broad band ranging from 2952 to 2869 cm^{–1}. Another significant observation is the presence of important analytical bands at 1737–1734 cm^{–1}, indicating the symmetric carbonyl group's ν(C=O) stretching vibration in the FT-IR spectrum. Additionally, strong characteristic bands in the region 1247–1246 cm^{–1} can be observed, which are assigned to the ν(C–O) vibration.

The FT-IR spectra of all synthesized compounds **9–12** exhibit a prominent feature characterized by bands at 2951–2866 cm^{–1}, which are assigned to the stretching vibrations of the ν(C–H) groups. Additionally, two strong characteristic bands appear in the regions of 1736–1733 and 1246–1228 cm^{–1}, which are attributed to the stretching vibrations of ν(C=O) and ν(C–O), respectively. Moreover, in the case of compound **9**

Figure 1. ^1H NMR spectra in the region (8.10–4.35 ppm) of the most characteristic signals of compounds (9–12).

a very strong band at 2099 cm^{-1} is observed, indicating the presence of $\nu(\text{N}=\text{N}^+=\text{N}^-)$ groups (Figure 2).

The ESI-MS spectra were acquired using methanol as the solvent. In all instances, the molecular ion $[\text{M}]^+$ is detected, indicating the presence of a positively charged ion with a proton, alkali metals, or halides in positive-ion mode (ES^+) as well as

negative-ion mode (ES^-). Figure 3 displays the ESI-MS spectrum of conjugates 11 and 12. In this spectrum, ion peaks are observed at m/z 1820 (20%) $[\text{C}_{99}\text{H}_{141}\text{N}_9\text{O}_{18}+2\text{K}+\text{H}]^+$, m/z 1768 (95%) $[\text{C}_{99}\text{H}_{141}\text{N}_9\text{O}_{18}+\text{Na}]^+$ (for compound 11), m/z 1942.2 (20%) $[\text{C}_{105}\text{H}_{147}\text{N}_9\text{O}_{24}+\text{Na}]^+$, and m/z 982.6 (100%) $[\text{C}_{105}\text{H}_{147}\text{N}_9\text{O}_{24}+2\text{Na}]^{2+}$ (for compound 12). Furthermore, for

Figure 2. FT-IR spectra of **9** (blue) and **10** (red) in the region (3700–400 cm^{-1}).

these compounds, the ESI-MS spectrum in negative-ion mode exhibits the molecular ion at m/z 1801 (55%) [$\text{C}_{99}\text{H}_{141}\text{N}_9\text{O}_{18}+\text{Hac}-\text{H}]^-$ (for **11**), m/z 2016.2 (100%) [$\text{C}_{105}\text{H}_{147}\text{N}_9\text{O}_{24}+\text{HSO}_4]^-$, m/z 1954.2 (25%) [$\text{C}_{105}\text{H}_{147}\text{N}_9\text{O}_{24}+\text{Cl}]^-$, and m/z 2030.2 (55%) [$\text{C}_{105}\text{H}_{147}\text{N}_9\text{O}_{24}+\text{TFA}-\text{H}]^-$ (for **12**) (Figure 3).

2.3. PM5 Calculations. The PM5 semiempirical calculations were performed using the WinMopac 2003 program. The final heat of formation (HOF) of compounds **5** and **6** as well as quasi-podands **9–13** are presented in Table 1.

The molecular models of compounds **4–6** as well as **9–12** are shown in Figure 4. For the substrates **4–6**, the lowest values of HOF are observed for cholic acid derivatives **6**, where an increasing number of acetoxy groups facilitate the formation of intramolecular hydrogen bonds. It is noteworthy that mono-substituted derivatives of bile acids-linked 1,2,3-triazole ring (with two N_3 groups) are not formed because the heat of formation is very high. Also, disubstituted derivatives are occasionally observed. Only lithocholic acid derivatives could be obtained, and their stability was still low (higher HOF than substrate **5**).

In all quasi-podands, we observed π – π stacking sandwich-type interactions between two triazole rings were observed. The calculated interplanar separation is about 5.8 Å. These distances are greater by about 1.7 Å in comparison to the classical π – π stacking interactions because the triazole ring is attached to directly a rigid aromatic ring which imposes an increasing distance. Furthermore, this spatial arrangement of bile acids and 1,2,3-triazole rings can facilitate the formation of stable host–guest complexes.

2.4. In Silico Biological Activity Studies. The pharmacological activity of the synthesized compounds **5**, **6**, and **9–12** has been assessed using computer-aided drug discovery methods, specifically employing the Prediction of Activity Spectra for Substances (PASSs) program. This program utilizes a comprehensive analysis of structure–activity relationships within a diverse training set containing approximately 60,000 biologically active compounds from various chemical series, encompassing around 4500 types of biological activity. By simply providing the structural formula of a chemical compound, the PASS prediction can be obtained, making it a valuable tool for initial investigations. Numerous instances exist where the implementation of the PASS approach has resulted in the identification of novel pharmacological agents.^{44–47}

Furthermore, the analysis of the biological activity spectra for the newly two synthesized esters presented in this study serves as a notable illustration of *in silico* investigations on chemical compounds. The PASS program was employed to predict the biological activity spectra for two substrates **5** and **6** and one specific compound, namely, compound **9**. Focusing on the potential compound with the highest probability (referred to as focal activities) (see Table 2), we identified several frequently predicted types of biological activity, including acylcarnitine hydrolase inhibitor, alkenylglycerophosphocholine hydrolase inhibitor, alkylacetyl glycerophosphatase inhibitor, dextranase inhibitor, and CYP2C and CYP2B6 substrates for **5** and **6**. On the other hand, for the quasi-podands, an activity of more than 60% but less than 70% was observed. The following can be mentioned here: glyceryl-ether monooxygenase inhibitor, antifertility (female), antienzematic, cholesterol antagonist, as well as cytoprotectant. However, due to their molecular weight exceeding 1200 g/mol, the potential biological properties of compounds **10–12** could not be determined in this analysis.

2.5. Molecular Docking Studies. The macromolecular structure investigated in this study was identified by the PDB ID 1HW8. Below are the potential interactions observed between the analyzed structures and the protein domain. The graphical depictions illustrate the optimal ligand pose, determined by the binding site of the original ligands found within the raw PDB file 1HW8. These representations showcase the poses with the lowest binding energy observed inside the binding site. Figures 5–8 depict the interactions between the best poses of structures **9**, **10**, **11**, and **12**, respectively, and the protein domain of 1HW8.

For compound **9** (Figure 5), there exist three potential hydrogen bonds that could form between the ligand and the protein domain. The shortest among these potential interactions is identified between the ligand's keto ester oxygen and the hydrogen of residue SER 565 D, spanning a length of 2.07 Å. The second possible hydrogen bond measures 2.20 Å and involves the azide group's interaction with the hydrogen of residue ASP 690 C. The last interaction, furthest in distance, may occur between the ligand's nitrogen within the 1,2,3-triazole group and the SER 661 C residue of the protein.

For compound **10** (Figure 6), the potential number of hydrogen bonds is two. The shorter interaction, measuring 2.10 Å, occurs between the ligand's keto carboxyl oxygen and the hydrogen of residue ASN 810 D within the macromolecule.

According to the molecular docking studies, compound **11** (Figure 7) has the potential to form a total of four hydrogen bonds. These interactions are ranked in descending order of length:

- Another interaction involves the ligand's ester oxygen forming a bond (2.42 Å) with the hydrogen of ASN 755 C, which competes with the hydrogen bond formation between the same ligand's keto ester oxygen and the hydrogen of LYS 691 D residue (2.08 Å). The latter interaction is more favorable due to its shorter length.
- Additionally, another hydrogen bond is possible between another ligand's keto ester oxygen and the hydrogen of ARG 627 D, measuring 2.41 Å.
- The shortest hydrogen bond for compound **11** spans a length of 1.78 Å and can be established between yet another ligand's keto ester oxygen and the hydrogen of residue GLY 656 D.

The final compound investigated, ligand **12** (Figure 8), has the potential to form a total of five hydrogen bonds. However,

Figure 3. ESI-MS spectrum of conjugates 11 and 12.

four of these interactions compete with each other, resulting in the effective formation of three hydrogen bonds. The longest possible hydrogen bond exists between the ligand's ester oxygen atom and the hydrogen of residue ASN 658 D.

Another competitive interaction involves the hydrogen of residue GLN 815 D forming a bond (2.40 Å) with the ketone oxygen of one of the ester groups. Additionally, an interaction occurs between the ether's oxygen within the ligand's ester

group and the same hydrogen of the protein domain, measuring 2.25 Å. These interactions possess similar probabilities of formation due to their closely matching lengths.

The remaining two hydrogen bonds can be established between the ligand's ester keto oxygen and the hydrogen of residue ARG 590 D (2.20 Å in length), as well as between the same oxygen atom of the ligand and a different residue, namely,

Table 1. Heat of Formation (HOF) [kcal/mol] of Compounds 5, 6, and 9–13

compound	heat of formation[kcal/mol]
4	−212.7209
5	−298.6465
6	−383.8356
9	−286.8410
10	−550.9153
11	−809.8199
12	−1063.6189

SER 661 D. These interactions similarly exhibit very close probabilities of formation.

The docked molecules exhibit a higher affinity toward the 1HW8 protein domain compared to the cocrystallized ligand, which demonstrated a binding energy of -7.5 kcal/mol, with an average binding energy of -6.2 kcal/mol. Similarly, they display a higher affinity compared to mevastatin, showing a binding energy of -6.9 kcal/mol, with an average binding energy of -6.8 kcal/mol. This suggests that these molecules have the potential to serve as effective inhibitors. However, it is essential to note that the sizes of ligands **9** through **12** are notably larger than those of the known activity inhibitors used for comparison,

potentially influencing the sensitivity of this comparison. Figures 5–8 display binding energies, denoted in kcal/mol units (specified in the figures' descriptions).

3. CONCLUSIONS

In summary, an efficient synthesis of two new propiolic derivatives and four innovative bile acid bioconjugates with 1,2,3-triazole rings (compounds **9**–**12**) was designed using the “click” chemistry method. The reaction of propiolic or acyl propionic bile acid derivatives with 1,3,5-tris(azidomethyl)-benzene in a mixture of *tert*-butanol/methanol with the addition of sodium ascorbate and $\text{CuSO}_4 \cdot 5 \text{H}_2\text{O}$ at 60 – 65 °C yielded macrocyclic compounds containing rings 1,2,3-triazoles. The newly synthesized compounds were thoroughly characterized using spectroscopic techniques and molecular structure analysis. Additionally, the performed molecular docking indicates the potential inhibitory properties of the obtained structures. The Nobel Prize in Chemistry awarded for the study of “click” chemistry serves as conclusive evidence of the significance of this approach in organic synthesis. The growing interest in utilizing “click” chemistry for the synthesis of novel bioconjugates involving bile acids and sterols has a profound impact on the advancement of supramolecular chemistry, pharmacology, and

medicine. The design and preparation of compounds incorporating the 1,2,3-triazole ring offer immense biological potential and a diverse range of physicochemical properties, enabling their application as artificial receptors, organogels, and novel complexing and drug delivery agents.

4. EXPERIMENTAL SECTION

4.1. Synthesis. **4.1.1. General Procedure for the Synthesis of Compounds 4–6.** The methyl esters of bile acids were prepared according to a previously described procedure. In the case of compounds 4, 5, or 6, the bile acids (1 equiv) were dissolved in 15 mL of dichloromethane. Subsequently, *p*-TsOH and propionic acid (3 equiv) were added to the solution, and the reaction was allowed to proceed for 24 h at room temperature. After completion of the reaction, the mixture was subjected to a series of purification steps. It was first washed with cool water, followed by extraction with chloroform (20 mL). The chloroform layer was then washed with water and brine, and dried using Na₂SO₄. Finally, the solvent was removed under reduced pressure, yielding the following product yields: (45%) for 4, (57%) for 5, and (30%) for 6.

4.1.2. General Procedure for the Synthesis of Compounds 9–10. 1,3,5-Tris(azidomethyl)benzene (30 mg, 0.123 mmol) was dissolved in a mixture of *tert*-butanol and methanol (12 mL, 5:1). Propionic lithocholic ester (163 mg, 0.369 mmol) was then added, and the resulting mixture was heated at 60–65 °C (in a water bath) for 30 min. Next, to the homogeneous solution, CuSO₄·5H₂O (3 mg, 3 mol %) and sodium ascorbate (9 mg, 20 mol %) in water (0.3 mL) were added. The mixture was further heated to 60–65 °C (in a water bath) for 4 h. The resulting mixture was extracted with chloroform (10 mL), washed with brine (15 mL), and dried using anhydrous Na₂SO₄. After evaporating the solvent and purifying the residue over silica gel (CHCl₃/EtOAc, 25:1), 20.3 mg (11%) of product 9 and 169.7 mg (88%) of product 10 were obtained.

Methyl 3 α -Propynoyloxy-12 α -acetoxo-5 β -cholan-24-oate (5). Oil (130 mg, 57%). ¹H NMR (400 MHz, CDCl₃): δ ppm 5.08 (s, 1H, 12 β -H), 4.88–4.80 (m, 1H, 3 β -H), 3.66 (s, 3H, –OCH₃), 2.89 (s, 1H, –

C $\equiv$ CH), 2.11 (s, 3H, 12 α -OAc), 0.91 (s, 3H, CH₃-19), 0.80 (d, *J* = 6.3 Hz, 3H, CH₃-21), 0.72 (s, 3H, CH₃-18). ¹³C {¹H} NMR (101 MHz, CDCl₃) δ 174.6 (C-24), 170.5 (CO-12 α), 152.1 (C-26), 75.8 (C-12), 75.8 ($\equiv$ CH), 75.0 (C-3), 74.2 (–C $\equiv$), 51.5 (C-25), 49.3, 47.5, 45.0, 41.8, 35.6, 34.6, 34.6, 34.4, 34.0, 31.9, 30.9, 30.8, 27.2, 26.8, 26.3, 25.8, 25.6, 23.4, 23.0 (C-19), 21.4 (OAc-12 α), 17.5 (C-21), 12.4 (C-18). FT-IR (KBr, cm^{–1}) ν_{max} : 3445, 3251, 2938, 2869, 2112, 1734, 1701, 1377, 1246, 1194. ESI-MS *m/z*: 523 [M + Na]⁺, 539 [M + K]⁺.

Methyl 3 α -Propynoyloxy-7 α ,12 α -diacetoxo-5 β -cholan-24-oate (6). Oil (153 mg, 30%). ¹H NMR (400 MHz, CDCl₃): δ ppm 5.09 (s, 1H, 12 β -H), 4.92–4.91 (d, *J* = 3.1 Hz, 1H, 7 β -H), 4.76–4.68 (m, 1H, 3 β -H), 3.66 (s, 3H, –OCH₃), 2.91 (s, 1H, –C $\equiv$ CH), 2.15 (s, 1H, 7 α -OAc), 2.09 (s, 1H, 12 α -OAc), 0.92 (s, 3H, CH₃-19), 0.81 (d, *J* = 6.4 Hz, 3H, CH₃-21), 0.73 (s, 3H, CH₃-18). ¹³C {¹H} NMR (101 MHz, CDCl₃) δ 174.5 (C-24), 170.5 (CO-12 α), 170.4 (CO-7 α), 152.0 (C-26), 75.3 (C-12), 75.3 ($\equiv$ CH), 75.0 (C-3), 74.4 (–C $\equiv$), 70.5 (C-7), 51.2 (C-25), 47.3, 45.0, 43.4, 40.9, 37.7, 34.6, 34.5, 34.3, 34.2, 31.2, 30.8, 30.7, 29.7, 28.9, 27.1, 26.5, 25.6, 22.8, 22.4 (C-19), 21.6 (OAc-7 α), 21.5 (OAc-12 α), 17.5 (C-21), 12.2 (C-18). FT-IR (KBr, cm^{–1}) ν_{max} : 3247, 2952, 2873, 2116, 1737, 1439, 1378, 1247. ESI-MS *m/z*: 581 [M + Na]⁺, 597 [M + K]⁺, 594 [M + Cl][–].

1-Azidomethylene-3,5-di[2-(methyl 5 β -cholan-24-oate)-2-oxoethyl-1H-1,2,3-triazole-4-(3-carboxylate)]benzene (9). Oil (34 mg, 11%). ¹H NMR (400 MHz, CDCl₃): δ ppm 8.06 (s, 2H, triazole ring), 7.22 and 7.19 (s, 3H, Ar–H), 5.59 (s, 4H, Ph–CH₂–triazole ring), 5.07–4.99 (m, 2H, 3 β -H), 4.37 (s, 2H, CH₂–N₃), 3.67 (s, 6H, –OCH₃) 0.95 (s, 6H, CH₃-19), 0.92 (d, *J* = 6.5 Hz, 6H, CH₃-21), 0.64 (s, 6H, CH₃-18). ¹³C {¹H} NMR (101 MHz, CDCl₃) δ 174.8 (C-24), 160.0 (C-26), 141.3 (C-27), 138.3 (Ar–CCH₂–triazole ring), 136.0 (Ar–CCH₂N₃), 127.9 (C-28), 127.5 (C–Ar), 127.2 (C–Ar), 75.7 (C-3), 56.4, 56.0, 53.8 (C-29), 53.7 (C-29'), 51.5 (C-25), 42.7, 41.9, 40.4, 40.1, 35.8, 35.3, 35.0, 34.6, 32.1, 31.0, 28.2, 27.0, 26.5, 26.4, 26.3, 24.2, 23.2 (C-19), 20.8, 18.2 (C-21), 12.0 (C-18). FT-IR (KBr, cm^{–1}) ν_{max} : 2933, 2866, 2099, 1733, 1228, 1203, 1043. ESI-MS (*m/z*): 1225 [C₆₅H₉₃N₉O₈+HSO₄][–], 393 [C₆₅H₉₃N₉O₈+H+2Na]³⁺, 413 [C₆₅H₉₃N₉O₈+3K]³⁺, 565 [C₆₅H₉₃N₉O₈+2H]²⁺.

1,3,5-Tris[2-(methyl 5 β -cholan-24-oate)-2-oxoethyl-1H-1,2,3-triazole-4-(3-carboxylate)]benzene (10). Crystal (170 mg, 88%), mp 130–133 °C. ¹H NMR (400 MHz, CDCl₃): δ ppm 8.06 (s, 3H, triazole ring), 7.20 (s, 3H, Ar–H), 5.55 (s, 6H, Ph–CH₂–triazole ring), 5.07–4.99 (m, 3H, 12 β -H), 5.05–4.96 (m, 3H, 3 β -H), 3.67 (s, 9H, OCH₃), 2.12 (s, 9H, 12 α -OAc), 0.94 (s, 9H, CH₃-19), 0.80 (d, *J* = 6.5 Hz, 9H, CH₃-21), 0.65 (s, 9H, CH₃-18). ¹³C {¹H} NMR (101 MHz, CDCl₃) δ 174.7 (C-24), 160.0 (C-26), 141.4 (C-27), 136.6 (Ar–C), 127.8 (CH–Ar), 127.5 (C-28), 75.8 (C-3), 56.4, 56.0, 53.4 (C-29), 51.5 (C-25), 42.7, 41.9, 40.3, 40.1, 35.8, 35.3, 35.0, 34.6, 32.1, 31.0, 31.0, 28.1, 27.0, 26.5, 26.3, 24.2, 23.2 (C-19), 21.0, 18.2 (C-21), 14.2, 12.0 (C-18). FT-IR (KBr, cm^{–1}) ν_{max} : 2939, 2866, 1736, 1228, 1040. ESI-MS (*m/z*): 533 [C₉₃H₁₃₅N₉O₁₂+2H+Na]³⁺, 810 [C₉₃H₁₃₅N₉O₁₂+2Na]²⁺.

1,3,5-Tris[2-(methyl 12 α -acetoxo-5 β -cholan-24-oate)-2-oxoethyl-1H-1,2,3-triazole-4-(3-carboxylate)]benzene (11). Crystal (138 mg, 77%), mp 136–139 °C. ¹H NMR (400 MHz, CDCl₃): δ ppm 8.08 (s, 3H, triazole ring), 7.19 (s, 3H, Ar–H), 5.55 (s, 6H, Ph–CH₂–triazole ring), 5.07 (d, 3H, 12 β -H), 5.05–4.96 (m, 3H, 3 β -H), 3.67 (s, 9H, OCH₃), 2.12 (s, 9H, 12 α -OAc), 0.94 (s, 9H, CH₃-19), 0.80 (d, *J* = 6.3 Hz, 9H, CH₃-21), 0.73 (s, 9H, CH₃-18). ¹³C {¹H} NMR (101 MHz, CDCl₃) δ 174.6 (C-24), 170.7 (C-31), 160.0 (C-26), 141.4 (C-27), 136.5 (Ar–C), 127.8 (Ar–CH), 127.7 (C-28), 75.8 (C-3 and C-12), 53.4 (C-29), 51.5 (C-25), 49.3, 47.5, 45.0, 42.0, 36.5, 34.2, 32.2, 30.9, 30.8, 27.3, 27.0, 26.6, 25.7, 23.4 (C-19), 23.1, 21.5 (OAc-12 α), 17.5 (C-21), 12.4 (C-18). 1,3,5-Tris[2-(methyl 7 α ,12 α -diacetoxo-5 β -cholan-24-oate)-2-oxoethyl-1H-1,2,3-triazole-4-(3-carboxylate)]benzene (12). Crystal (176 mg, 57% yield), mp 136–139 °C. ¹H NMR (400 MHz, CDCl₃): δ ppm 8.10 (s, 3H, triazole ring), 7.21 (s, 3H, Ar–H), 5.55 (s, 6H, Ph–CH₂–triazole ring), 5.09 (d, 3H, 12 β -H), 4.94–4.81 (m, 6H, 3 β -H i 7 β -H), 3.67 (s, 9H, OCH₃), 2.20 (s, 9H, 7 α -OAc), 2.08 (s, 9H, 12 α -OAc), 0.95 (s, 9H, CH₃-19), 0.81 (d, *J* = 6.2 Hz, 9H, CH₃-21),

Figure 5. Ligand **9** possible hydrogen bonds between 1HW8 protein domain binding site. The binding energy equals -8.7 kcal/mol, with the average binding energy of -8.4 kcal/mol.

Figure 6. Ligand 10 possible hydrogen bonds between 1HW8 protein domain binding site. The binding energy equals -9.8 kcal/mol, with the average binding energy of -9.8 kcal/mol.

Figure 7. Ligand 11 possible hydrogen bonds between 1HW8 protein domain binding site. The binding energy equals -8.9 kcal/mol, with the average binding energy of -9.0 kcal/mol.

Figure 8. Ligand 12 possible hydrogen bonds between 1HW8 protein domain binding site. The binding energy equals -9.2 kcal/mol, with the average binding energy of -9.1 kcal/mol.

0.73 (s, 9H, CH_3 -18). ^{13}C $\{^1\text{H}\}$ NMR (101 MHz, CDCl_3) δ 174.5 (C-24), 170.8 (C-33), 170.6 (C-31), 160.1 (C-26), 141.4 (C-27), 136.5 (C-Ar), 128.0 (C-28 i CH-Ar), 75.7 (C-12), 75.3 (C-3), 70.5 (C-7), 53.4 (C-29), 51.5 (C-25), 47.3, 45.1, 43.4, 41.0, 37.7, 34.6, 31.3, 31.8, 30.7, 29.0, 27.1, 26.7, 25.7, 22.8 (C-19), 22.5 (OAc-7 α), 21.7 (OAc-12 α), 17.4 (C-21), 12.2 (C-18). FT-IR (KBr, cm^{-1}) ν_{max} : 2951, 2872, 1735, 1378, 1246, 1022. ESI-MS (m/z): 2016.2 [$\text{C}_{105}\text{H}_{147}\text{N}_9\text{O}_{24} + \text{HSO}_4$] $^-$, 1954.2 [$\text{C}_{105}\text{H}_{147}\text{N}_9\text{O}_{24} + \text{Cl}$] $^-$, 1942.2 [$\text{C}_{105}\text{H}_{147}\text{N}_9\text{O}_{24} + \text{Na}$] $^+$, 982.6 [$\text{M} + 2\text{Na}$] $^{2+}$, 2030.2 [$\text{C}_{105}\text{H}_{147}\text{N}_9\text{O}_{24} + \text{TFA} - \text{H}$] $^-$.

4.2. Molecular Docking Studies. The molecular docking process utilized the OpenBabel software^{48,49} to generate three-dimensional (3D) structures from SMILES representations of compounds. These structures were initially saved in *.pdb format and subsequently converted to the required *.pdbqt format for compatibility with the AutoDock Vina algorithm.⁵⁰ The receptor, represented by 1HW8 (PDB ID, HMG-CoA reductase), was prepared using AutoDock Tools 1.5.7.^{51,52} The molecular docking methodology employed the AutoDock Vina algorithm utilizing the multiple CPU technique.⁴⁹ Visualizations of the best poses of the docked ligands and potential

hydrogen bond formations were performed using the Chimera tool (version 1.16).⁵³

In this study, the receptor 1HW8 (PDB ID, HMG-CoA reductase) was selected for docking structures **9**, **10**, **11**, and **12** (refer to Figure 8), acquired from the Protein Data Bank (PDB).^{54–56} This enzyme is pivotal in cholesterol production within the liver. Inhibiting the HMG-CoA reductase activity can potentially reduce cholesterol production, subsequently lowering its concentration in the bloodstream.⁵⁶

The docked structures were targeted to the active site of the protein domain, analogous to the cocrystallized ligands. The search parameters utilized for 1HW8 were set as follows: center (x, y, z): 22.145, 21.402, 29.764, and size (x, y, z) ($80 \times 80 \times 80$) Å³.

ABSTRACT

New six steroid conjugates have been prepared from bile acids (tail part) and sterol (head part) derivatives using click chemistry method. The azide-alkyne Huisgen cycloaddition (intermolecular 1,3-dipolar cycloaddition) of the azide derivatives of lithocholic, deoxycholic, cholic acid and propiolate ester of cholesterol and cholestanol gave a new bile acid–sterol conjugates linked with a 1,2,3-triazole ring. Previously, bile acids were converted into bromoacetyl substituted derivatives by the reaction of propargyl esters of deoxycholic and cholic acids as well as 5 α -cholestan-3-yl-propynoate were also obtained and characterized for the first time. All conjugates were obtained in good yields using an efficient synthesis method. The structures of all conjugates as well as four substrates were confirmed by spectral (¹H- and ¹³C NMR, and FT-IR) analysis, mass spectrometry (ESI-MS), as well as PM5 semiempirical methods. Also B3LYP calculations have been carried out. The screening constants for ¹³C and ¹H atoms have been calculated by the GIAO/B3LYP/6–311G(d,p) approach and analyzed. Theoretical vibrational parameters are compared with obtained experimental parameters. Estimation of the pharmacotherapeutic potential has been accomplished for the synthesized compounds on the basis of Prediction of Activity Spectra for Substances (PASS). Additionally molecular docking was performed for the selected conjugate.

1. Introduction

The properties of compounds of natural origin represent important benefits for organic chemistry. Steroids deserve special mention. They are chemical compounds that perform several functions ensuring the proper functioning of living organisms, such as participation in metabolic changes, components of plant and animal cell membranes, and a precursor to the production of many vitamins [1–7]. Transformation of the cholesterol structure under the influence of UV radiation leads to obtaining 1 α ,25-dihydroxycalciferol (vitamin D3) [8–10]. In addition, special attention is drawn to bile acids, plant sterols (ergosterol), sex hormones (estrogens, testosterone, progesterone), plant hormones (brassinosteroids) [11–13]. Organic syntheses, in which different functional groups attached to the core of all steroid compounds of the cyclopentanoperhy-

drophenanthrene skeleton are modified, lead to the production of derivatives with significantly higher biological activity [14–20].

Bile acids were isolated in 1828 by L. Gmelin from whale bile. The starting compound for their receipt in the liver is cholesterol. After biosynthesis, they form derivatives with the amino acids taurine and glycine and are stored in the form of salts in the gallbladder [21–24]. Bile acids are distinguished by a large curved skeleton, A/B rings adopting *cis* geometry, enantiomeric purity, chirality, and the presence of hydroxyl groups in a different position at carbon atoms (3 α ; 3 α , 7 α ; 3 α , 7 α , 12 α) [25–27]. Polarity, amphiphilic properties and high reactivity of hydroxide groups, varying respectively in the order of 3 α > 7 α > 12 α , make these compounds have enormous potential as a precursor to the synthesis of organic macrocyclic steroid conjugates with high pharmacotherapeutic activity [28–34].

The possibility of modifying the 3 α -OH group contributed to the increase in interest in bile acid and sterol derivatives, especially in the synthesis of dimers, molecular pliers, artificial receptors, cholophans or quasi-podands [35–42].

“Click chemistry” is an innovative and modern method of synthesizing new steroid conjugates gaining importance in the pharmaceutical industry and medicine. The copper-alkyne azido-alkyne addition (CuAAC) described by K.B. Sharpless involves the formation of a new carbon-heteroatom bond in the ring [43–47]. Obtaining new conjugates by the “click” method is primarily a highly efficient, selective and effective synthesis. In addition, the resulting products are easy to isolate, stable in many solvents, including water, and resistant to metabolic degradation [44,48]. The 1,3-dipolar cycloaddition is crucial. The Huisgen reaction occurs in the presence of Cu(I) between terminal alkyne and azide. It is an extremely valuable method of synthesis of compounds containing 1,2,3-triazole rings [48–52]. The use of an appropriate catalyst and increased temperature determine the regioselectivity of the reaction, leading to the formation of 1,4- or 1,5-disubstituted 1,2,3-triazoles [53–57]. Conjugates containing 1,2,3-triazole rings in the structure have several important properties, especially they are distinguished by high resistance to oxidation reactions, reduction and hydrolysis of biological systems, invulnerability to metabolic degradation, anti-cancer activity and the possibility of forming hydrogen bonds [31,34,43,58–60].

2. Experimental

2.1. Instrumentation and chemicals

All of the synthesis reagents lithocholic, deoxycholic and cholic acids, cholesterol, cholestanol, acetic anhydride, pyridine, propionic acid, sodium azide, sodium ascorbate were purchased from Sigma-Aldrich Corporation. Solvents chloroform, dichloromethane, toluene, hexane, *t*-butanol, methanol were obtained from common commercial sources (Merck, Fisher) and used without purification. General. IR Spectra: FT/IR-4600 type A in solid state or oil; ν in cm^{-1} . ^1H and ^{13}C NMR spectra: Varian Mercury 300 MHz spectrometer (Oxford, UK), operating at 300.07 and 75.4614 for ^1H and ^{13}C , resp.; δ in ppm rel. to Me_4Si as internal standard, J in Hz. Typical conditions for the H-atom spectra: pulse width 32° , acquisition time 5 s, FT size 32 K and digital resolution 0.3 Hz per point; and for the C-atom spectra: pulse width 60° , FT size 60 K and digital resolution 0.6 Hz per point, the number of scans varied from 1200 to 10,000 per spectrum. ESI-MS: Waters/Micromass (Manchester, UK) ZQ mass spectrometer equipped with a Harvard Apparatus (Saint Laurent, Canada), syringe pump; in m/z . The sample solns. were prepared in MeOH at the concentration of ca. 10^{-5} M. The standard ESI-MS mass spectra were recorded at the cone voltage 90 V.

2.2. Synthesis

Procedure for methyl esters of bile acids as well as their acetoxy derivatives (**4–6**) was described earlier. Procedure for 3-bromoacetoxy derivatives of bile acids (**7–9**): methyl 5 β -cholan-24-oate (**4**), methyl 12 α -acetoxy-5 β -cholan-24-oate (**5**) or methyl 7 α ,12 α -diacetoxy-5 β -cholan-24-oate (**6**) was dissolved in 5 mL of anhydrous dichloromethane, and then subsequently, bromoacetic acid bromide was added drop wise and the reaction mixture was kept at room temperature for 24 h. Then the mixture was washed with NaHCO_3 (5%, 20 mL), brine (200 mL) and finally dried over Na_2CO_3 . The solvent was evaporated under reduced pressure to give the crude product. Products were purified by chromatography on silica gel (Merck, type 60, 70–230 mesh) with chloroform/hexane as eluent and to give the products 50% of (**7**), 92% (**8**) and 70% of (**9**). Procedure for 3-azidoacetoxy derivatives of bile acids (**10–12**): 3-bromoacetoxy derivatives of bile acids (**7–9**) were dissolved in 15 mL of THF. Then, NaN_3 was added, the

mixture was heated at 50 $^\circ\text{C}$ for 4 h. DMF was evaporated, extracted with toluene, washed with brine, and dried (Na_2SO_4) and to give the products 95% of (**10**), 88.6% (**11**) and 78% of (**12**). The sterols (cholesterol **13** or cholestanol **14**) was dissolved in 15 mL of dichloromethane, then *p*-TsOH and propionic acid was added and the reaction was carried out for 24 h at room temperature. Next the mixture washed with cool water, extracted ethyl acetate and washed with water, brine, and dried (Na_2SO_4). The solvent was evaporated under reduced pressure to give the products: (53%) of (**15**) and (72%) of (**16**). Procedure for dimers of bile acids and sterols derivatives (**17–22**): compounds (**10–12**) was dissolved in a mixture of *t*-BuOH/ MeOH (6 mL, 5:1). Then, 5-cholesten-3 β -ol 3-propiolate (**15**) or 5-cholestan-3 β -ol 3-propiolate (**16**) was added. Next, to the homogenous mixture were added $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ (3 mg, 3 mol%) and sodium ascorbate (9 mg, 20 mol%) in water (0.3 mL). The reaction mixture was heated at 60 $^\circ\text{C}$ for 8 h and then extracted with chloroform, washed with brine and dried over anhydrous Na_2SO_4 . The crude compound was purified by column chromatography on silica gel using chloroform/ethyl acetate (5:1) as an eluent.

2.3. Chemical characterization

2.3.1. Methyl 3 α -bromoacetoxy-12 α -acetoxy-5 β -cholan-24-oate (**8**)

White solid (92.7%), melting point: 119–120 $^\circ\text{C}$. ^1H NMR (400 MHz, CDCl_3) δ : 5.09 (d, $J = 3.0$ Hz, 1H, 12 β -H), 4.81–4.72 (m, 1H, 3 β -H), 3.81 (s, 2H, CH_2 -27), 3.66 (s, 3H, CH_3 -25), 2.10 (s, 3H, 12-OAc), 0.91 (s, 3H, CH_3 -19), 0.81 (d, $J = 6.3$ Hz, 3H, CH_3 -21), 0.73 (s, 3H, CH_3 -18). ^{13}C NMR (101 MHz, CDCl_3) δ : 174.57 (C-24), 170.45 (12 α -CO), 166.71 (C-26), 76.32 (C-12), 75.84 (C-3), 51.49 (C-25), 49.39, 47.54, 44.97, 41.75, 35.60, 34.67, 34.55, 34.35, 33.97, 31.84, 30.94, 30.90, 30.79, 27.30 (C-27), 26.78, 26.34, 26.32, 26.29, 25.79, 25.58, 23.38, 22.97 (C-19), 21.34 (12 α -COCH₃), 17.47 (C-21), 12.37 (C-18). FT-IR (KBr) ν_{max} , cm^{-1} : 2936, 2865, 1733, 1281, 1250. ESI-MS (MeOH) m/z (%): 591 (100) $[\text{M}+\text{Na}]^+$, 607 (15) $[\text{M} + \text{K}]^+$.

2.3.2. Methyl 3 α -bromoacetoxy-7 α ,12 α -diacetoxy-5 β -cholan-24-oate (**9**)

Oil (70%). ^1H NMR (400 MHz, CDCl_3) δ : 5.09 (t, $J = 2.8$ Hz, 1H, 12 β -H), 4.91 (d, $J = 3.1$ Hz, 1H, 7 β -H), 4.69–4.61 (m, 1H, 3 β -H), 3.81 (d, $J = 0.6$ Hz, 2H, CH_2 -27), 3.66 (s, 3H, CH_3 -25), 2.15 (s, 3H, 7-OAc), 2.09 (s, 3H, 12-OAc), 0.92 (s, 3H, CH_3 -19), 0.81 (d, $J = 6.4$ Hz, 3H, CH_3 -21), 0.73 (s, 3H, CH_3 -18). ^{13}C NMR (101 MHz, CDCl_3) δ : 174.50 (C-24), 170.50 (12 α -CO), 170.31 (7 α -CO), 166.74 (C-26), 76.06 (C-12), 75.32 (C-3), 70.61 (C-7), 51.51 (C-25), 47.33, 45.02, 43.35, 40.80, 37.69, 34.57, 34.43, 34.27, 34.22, 31.13, 30.85, 30.73, 28.86 (C-27), 27.15, 26.51, 26.28, 25.52, 22.76, 22.48 (C-19), 21.58 (12 α -COCH₃), 21.40 (7 α -COCH₃), 17.46 (C-21), 12.19 (C-18). FT-IR (KBr) ν_{max} , cm^{-1} : 1734, 1283, 1248. ESI-MS (MeOH) m/z (%): 651 (100) $[\text{M}+\text{Na}]^+$.

2.3.3. Methyl 3 α -azidoacetoxy-12 α -acetoxy-5 β -cholan-24-oate (**11**)

White solid (88.6%), melting point: 129–131 $^\circ\text{C}$. ^1H NMR (400 MHz, CDCl_3) δ : 5.09 (d, $J = 3$ Hz, 1H, 12 β -H), 4.88–4.78 (m, 1H, 3 β -H), 3.84 (s, 2H, CH_2 -27), 3.66 (s, 3H, CH_3 -25), 2.09 (s, 3H, 12-OAc), 0.92 (s, 3H, CH_3 -19), 0.81 (d, $J = 6.3$ Hz, 3H, CH_3 -21), 0.73 (s, 3H, CH_3 -18). ^{13}C NMR (101 MHz, CDCl_3) δ : 174.57 (C-24), 170.43 (12 α -CO), 167.70 (C-26), 76.13 (C-12), 75.83 (C-3), 51.47 (C-25), 50.54 (C-27), 49.40, 47.55, 44.98, 41.76, 35.60, 34.67, 34.58, 34.35, 33.96, 32.08, 30.95, 30.80, 27.30, 26.77, 26.51, 25.81, 25.57, 23.38, 22.95 (C-19), 21.28 (12 α -COCH₃), 17.47 (C-21), 12.37 (C-18). FT-IR (KBr) ν_{max} , cm^{-1} : 2106, 1733, 1281, 1256, 1235, 1198. ESI-MS (MeOH) m/z (%): 554 (100) $[\text{M}+\text{Na}]^+$, 570 (10) $[\text{M} + \text{K}]^+$.

2.3.4. Methyl 3 α -azidoacetoxo-7 α ,12 α -diacetoxo-5 β -cholan-24-oate (12)

Oil (78%). ^1H NMR (400 MHz, CDCl_3) δ : 5.09 (t, J = 2.8 Hz, 1H, 12 β -H), 4.92 (d, J = 3.0 Hz, 1H, 7 β -H), 4.74–4.66 (m, 1H, 3 β -H), 3.85 (d, J = 1.8 Hz, 2H, CH_2 -27), 3.66 (s, 3H, CH_3 -25), 2.13 (s, 3H, 12-OAc), 2.08 (s, s, 3H, 7-OAc), 0.93 (s, 3H, CH_3 -19), 0.82 (d, J = 6.4 Hz, 3H, CH_3 -21), 0.73 (s, 3H, CH_3 -18). ^{13}C NMR (101 MHz, CDCl_3) δ : 174.48 (C-24), 170.44 (12 α -CO), 170.28 (7 α -CO), 167.63 (C-26), 75.90 (C-12), 75.30 (C-3), 70.60 (C-7), 51.48 (C-25), 50.56 (C-27), 47.34, 45.02, 43.32, 40.85, 37.72, 34.58, 34.51, 34.45, 34.25, 31.17, 30.86, 30.74, 28.81, 27.14, 26.75, 25.48, 22.78, 22.44 (C-19), 21.50 (12 α -COCH $_3$), 21.30 (7 α -COCH $_3$), 17.47 (C-21), 12.18 (C-18). FT-IR (KBr) ν_{max} , cm^{-1} : 2111, 1732, 1243, 1202. ESI-MS (MeOH) m/z (%): 612 (100) $[\text{M}+\text{Na}]^+$.

2.3.5. 5-cholestan-3 β -ol 3-propiolate (16)

Oil (72%). ^1H NMR (300 MHz, CDCl_3) δ : 4.81–4.73 (m, 1H, 3'-H), 2.85 (s, 1H, CH-30), 0.90 (d, J = 6.5 Hz, 3H, CH_3 -21'), 0.86 (dd, J_1 = 6.6, J_2 = 1.4 Hz, 6H, CH_3 -26' and CH_3 -27'), 0.82 (s, 3H, CH_3 -19'), 0.64 (s, 3H, CH_3 -18'). ^{13}C NMR (CDCl_3) δ : 152.29 (C-28), 77.20, 76.37 (C-30), 75.12 (C-29), 74.03 (C-3'), 56.35, 56.21, 54.11, 44.61, 42.55, 39.91, 39.48, 36.63, 36.13, 35.78, 35.40, 33.94, 33.63, 31.92, 28.52, 28.22, 28.00, 27.17, 24.17, 23.81, 22.82 (C-19'), 22.55 (C-27'), 21.17 (C-26'), 18.64 (C-21'), 12.17, 12.05 (C-18'). 2.4. Theoretical calculations

The PM5 semiempirical calculations were performed using the WinMopac 2003 program. The final heat of formation (HOF) for dimers of bile acids and sterols derivatives (17–22) linked 1,2,3-triazole ring is presented in Table 5. The molecular models of compounds all compounds are shown in Figs. 3 and 4. The calculations were performed using the Gaussian 09 program package [61] and B3LYP [62,63] method in conjunction with 6–311G(d,p) [64] basis set. The magnetic isotropic shielding tensors were calculated using the standard GIAO/B3LYP/6–311G(d,p) (Gauge-Independent Atomic Orbital) approach [65,66].

2.5. Docking experiments

Docking experiments were performed using Flare application available in Cresset Software [67]. Downloaded target pdb's from PDB protein data bank [68] were prepared in protein preparation module using normal calculating mode. Active site size was set at 6 Å. Ligands were prepared according to automatic settings. Docking calculations were performed according to very accurate but slow method. Grid box was centered on co-crystallized ligand. Number of runs was set at 8 and max poses at 10.

3. Results and discussion

In our previous work we described the synthesis method and characterization bile acid-sterol conjugates linked with a 1,2,3-triazole ring of propargyl esters of lithocholic, deoxycholic as well as cholic acids and ergo ster-3 β -yl 2-azidoacetate and cholesterol-3 β -yl 2-azidoacetate [69]. To the best of our knowledge, no work has been published on the synthesis or the physicochemical properties of 3-bromoacetoxy (8,9) and 3-azidoacetoxy derivatives of methyl 12 α -acetoxy-5 β -cholan-24-oate (11) and methyl 7 α ,12 α -diacetoxy-5 β -cholan-24-oate (12), 5-cholestan-3 β -ol 3-propiolate (16) as well as new six conjugates of connected in a head-to-tail fashion of 3-azidoacetoxy derivatives of bile acids (tail) and propiolate esters of sterols (head) linked by a 1,2,3-triazole ring (17–22). This type of combination is a completely innovative approach to the preparation and research of a new type of steroid conjugates.

The structures of two bromoacetyl substituted derivatives of bile acids (8) and (9), azidoacetyl substituted derivatives of bile acids (11) and (12), 5-cholestan-3 β -ol 3-propiolate (16) as well as all synthesized conjugates (17–22) were determined on the basis of

their ^1H and ^{13}C NMR, FT-IR, and ESI-MS spectra. Moreover, PM5 and B3LYP calculation methods were performed for all compounds. The syntheses of substrates (8,9), (11,12) and (16), as well as conjugates (17–22), are shown in the Schemes 1 and 2, respectively.

3.1. Synthesis

The bile acid methyl esters, steroids bromoacetates and azidoacetates derivatives as well as propiolate esters of sterols were obtained with satisfactory yields. The methyl 3 α -bromoacetoxy-5 β -cholan-24-oate (7), methyl 3 α -bromoacetoxy-12 α -acetoxy-5 β -cholan-24-oate (8), methyl 3 α -bromoacetoxy-7 α ,12 α -diacetoxy-5 β -cholan-24-oate (9) was synthesized in the reaction of methyl esters of bile acids (4–6) with bromoacetic acid bromide in anhydrous dichloromethane. On the other hand methyl 3 α -azidoacetoxy-5 β -cholan-24-oate (10), methyl 3 α -azidoacetoxy-12 α -acetoxy-5 β -cholan-24-oate (11), methyl 3 α -azidoacetoxy-7 α ,12 α -diacetoxy-5 β -cholan-24-oate (12) was synthesized in the reaction of bromoacetate derivatives of bile acids via a substitution reaction with NaN_3 in DMF at 50°. This one-pot reaction leads to azide derivatives in very good yield. The estrification of cholesterol (13) or cholestanol (14) with propiolic acid in dichloromethane with *p*-TsOH presence gave 5-cholesten-3 β -ol 3-propiolate (15) and 5-cholestan-3 β -ol 3-propiolate (16). The azides of derivatives bile acids (10–12) and propargyl esters of sterols (15–16) were used as a substrates in the „click” chemistry reaction in the presence of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ and sodium ascorbate in *t*-BuOH/MeOH (5:1). A mixture of crude products (17–22) were obtained and separated by column chromatography. This reaction leads to dimers in satisfactory yields.

3.2. Spectroscopic study

3.2.1. Nuclear magnetic resonance spectroscopy

The three substrates methyl 3 α -bromoacetoxy-5 β -cholan-24-oate (7), methyl 3 α -azidoacetoxy-5 β -cholan-24-oate (10) and 5-cholesten-3 β -ol 3-propiolate (15) have been described and characterized in the literature [37,69]. The ^1H and ^{13}C NMR data of compounds (8), (9), (11), (12) and (17–22) are shown in Tables 1–3 respectively. The ^1H NMR spectra in the region of 5.45–4.60 ppm for the most characteristic signals of compounds (17–22) are shown in Fig. 1.

In the ^1H NMR spectrum of methyl 3 α -bromoacetoxy-12 α -acetoxy-5 β -cholan-24-oate (8), methyl 3 α -bromoacetoxy-7 α ,12 α -diacetoxy-5 β -cholan-24-oate (9), methyl 3 α -azidoacetoxy-12 α -acetoxy-5 β -cholan-24-oate (11) and methyl 3 α -azidoacetoxy-7 α ,12 α -diacetoxy-5 β -cholan-24-oate (12) showed characteristic two hydrogen singlets in the range 0.73 and 0.93–0.91 ppm and doublet at 0.82–0.81 ppm assigned to CH₃-18, CH₃-19, and CH₃-21, respectively. The protons of CH₃-25 gave characteristic signal at 3.66 ppm. The protons of the 7 α -CO₂CH₃ group gave signals in the range 2.15–2.13 ppm for compounds (9) and (12), and additionally 12 α -CO₂CH₃ group gave signals in the range 2.08–2.10 ppm for compounds (8), (9) and (11) and (12). For all compounds show characteristic multiplets in the range 4.88–4.61 ppm assigned to axial positions of the C3 β -H protons in steroid skeleton. In the spectrum of compounds (9) and (12) additionally is present positions of the C7 β -H proton in the range 4.92–4.91 ppm. However, in the case of these acetoxy derivatives protons of C12 β -H appear at 5.09 ppm. The ^1H NMR spectra of these compounds show characteristic singlets at 3.81 ppm for the protons of the 3 α -CO₂CH₂Br group, whereas for compound (8) and (9). In turn for compounds (11) and (12) the protons of the 3 α -CO₂CH₂N₃ group in the range 3.85–3.84 ppm. The proton of C $\equiv$ CH group in compound (16) gave signal at 2.85 ppm. Two hydrogen singlets at 0.64, 0.82 as well as

Scheme 1. Synthesis of bromoacetyl substituted derivatives of methyl esters of bile acids (7–9) and its azidoacetyl substituted derivatives (10–12) (a) as well as propargyl esters of cholesterol (15) and cholestanol (16) (b).

Table 1

characteristic doublets at 0.90 ppm are assigned to CH_3 –18', CH_3 –19', and CH_3 –21', respectively. The doublets of doublets of protons of CH_3 –26' and CH_3 –27' gave signal at 0.86 ppm. The equatorial proton in positions of the $C3\alpha$ –H proton in cholestanol skeleton gave signal in the range 4.81–4.75 ppm.

The diagnostics proton signals of the triazole ring $C28$ –H of all conjugates with 1,2,3-triazole ring (17–22) in $CDCl_3$ arise as a singlet at about 8.24–8.22 ppm. In turns, the protons of the methy-

lene groups $C27$ –H linked directly to the triazole ring give signals at about 5.22–5.17 ppm. The 1H NMR spectra of (17–22) showed characteristic multiplets of protons of $C3'\alpha$ –H of sterol skeleton in the range of 5.04–4.86 ppm. In the same range there are also multiplets from the protons of $C3\beta$ –H group of bile acid skeleton. In the spectra of compounds (18), (19) and (21) and (22) characteristic broad singlets in the range 5.09 ppm are observed which are due to the $C12\beta$ –H protons. 1H NMR spectra of conjugate (19)

Scheme 2. Synthesis of dimers of bile acids and sterols derivatives (17–22) linked by 1,2,3-triazole ring.

27'	0.87	0.87	0.87	0.86	0.86	0.86

show multiplets in the range of at 4.98–4.86 ppm but conjugate (22) gave singlet at 4.92 ppm assigned to the C7β-H protons of the bile acid skeleton. In the bile acids skeleton was observed two hydrogen singlets ranking from 0.73 to 0.66 and 0.93–0.91 ppm and characteristic doublet at 0.91–0.81 ppm assigned to CH₃–18, CH₃–19 and CH₃–21, respectively. On the other hand in the cholesterol part the characteristic hydrogen singlets in the range 0.69–0.65 and 1.05–0.85 ppm and doublet at 0.92–0.82 ppm assigned to CH₃–18', CH₃–19', and CH₃–21', respectively. The ¹H-NMR spectra of (17–22) showed a doublet at 0.87 or 0.86 ppm for the protons of the CH₃–26' and CH₃–27' methyl groups. For cholesterol derivatives (17–19) diagnostics is doublet for C6'-H at 5.42 ppm. Additionally in the ¹H NMR spectra of all conjugates show characteristic singlets in the range 2.14 ppm and 2.10–2.09 ppm for the protons of the 7α-CO₂CH₃ and 12α-CO₂CH₃ group, respectively. The

characteristic protons shifts for compounds (15–18) are collected in Table 3.

The ¹³C NMR spectra of compounds (8–9) and (11–12) show characteristic signals at 12.37–12.18, 22.97–22.44 and 17.47–17.46 ppm which are assigned to CH₃–18, CH₃–19 and CH₃–21, respectively. On the other hand, carbon atoms in carbonyl group of bromoacetoxy groups in positions 3α resonate in the range of 167.70–166.71 ppm. The carbon atoms of the C(12)=O steroid skeleton gave signals in the range of 170.50–170.43 ppm. However, carbon of the C(7)=O gave signal at 170.31–170.28 ppm. The diagnostics signal for CH₂Br groups in compounds (8–9) is observed at 28.86–27.30 ppm. Whereas the characteristic signal for CH₂N₃ groups in compounds (11–12) is observed at 50.56–50.54 ppm. Additionally for compound (16) were observed five signals from methyl groups CH₃–18', CH₃–19' and CH₃–21' as well as CH₃–26'

Fig. 1. ^1H NMR Spectra in the region of 5.45–4.65 ppm for the most characteristic signals of compounds (17–19).

26'	20.84	21.33	21.36	20.84	21.34	21.39
27'	21.05	21.02	21.01	21.22	21.18	21.22

and CH₃–27' at 12.05 ppm, 22.85 ppm, 18.64 ppm and 27.17 and 22.55, respectively. The carbon atoms of the HC≡C–CO₂ group are observed in the range 152.29 ppm, and 75.12 ppm as well as at 76.37 ppm are assigned to CO₂, C≡C–H respectively.

The ¹³C NMR spectra of dimers linked by 1,2,3-triazole ring in CDCl₃, showed signals at 12.38–12.03 ppm, 22.93–22.78 ppm, 18.28–17.47 ppm, which were assigned to CH₃–18, CH₃–19 and

CH₃–21 of bile acids parts, respectively. In the case of cholesterol parts, the signals of C-atoms of CH₃–18', CH₃–19' and CH₃–21' groups were situated in the ranges of 12.07–11.82, 22.55–22.53, and 18.71–18.63 ppm, respectively. The following characteristic shifts of methyl groups were present in the sterol side chain: CH₃–26' and CH₃–27' are positioned in the range of 21.39–20.84 ppm and 21.22–21.01 ppm.

Analytical differences in the ¹³C NMR spectra of the methyl groups of compound (**17**) and (**20**) are shown in Fig. 2. On the other hand, in the ¹³C NMR spectra of compounds (**17–22**), the signals of the C(27)H₂ groups appeared in the range of 51.21–51.13 ppm. The carbon atoms from triazole ring: C(28) as well as C(29) groups resonated at 128.83–128.69 ppm and 141.13–140.97 ppm, respectively.

The signals of C(24)=O, C(26)=O and C(30)=O, appeared in the range of 174.73–174.47 ppm, 165.14–165.08 ppm and 160.16–159.95 ppm, respectively. However, carbon atoms in C = O of acetoxy groups in positions 7α and 12α resonate in the range of 170.45–170.22 ppm.

3.2.2. Infrared spectroscopy

The most characteristic feature of the FT-IR spectra of compound (**16**) is band at 3284 cm^{−1} assigned to the ν(≡C–H) group. Regarding that the steroid skeleton is a saturated hydrocarbon, it doesn't provide many useful IR features. Strong stretching vibrations of C–H bonds are identified at 2933 cm^{−1} and 2865 cm^{−1}. For synthesized compounds (**10**), (**11**) and (**12**) are requisite and analytical bands at 2111–2106 cm^{−1}, which are specific attribute of ν(N = N⁺=N[−]) group. Moreover, for all substrates (**7–9**), (**10–12**) and (**15–16**) are also observed two strong characteristic bands at 1756–1707 cm^{−1} and 1283–1198 cm^{−1}, which are assigned respectively to the symmetric group ν(C = O) and ν(C–O). It worth mentioning that the most distinctive in the FT-IR spectra of conjugated steroids (**15–20**) are represented by ν(C = O) and ν(C–O) groups, two powerful bands in the 1743–1732 cm^{−1} and 1244–1211

Fig. 3. Molecular models of conformers *syn* (a) and *anti* (b) for conjugates (17–19) calculated by PM5 method.

cm^{-1} region, appropriately. In addition, characteristic stretching vibrations of C–H bonds are present in the $2946\text{--}2867\text{ cm}^{-1}$.

3.3. PM5 and B3LYP calculations

PM5 semiempirical calculations were performed using the WinMopac 2003 program. The molecular models of all conjugates are shown in Fig. 3. Representative conjugates (19) of bile acids in conformers *syn* and *anti* are shown in Fig. 4. The final heats of formation (HOF) for the bile acids (1–3), cholesterol (13) and cholestanol (14) as well as their conjugates (17–22) are presented in Table 4. It is worth mentioning that, in many works that describe the application of computational methods, one can find information on the comparison of theoretical results with crystallographic structures. Not without significance is the use of computational methods in determining the properties of the docking [70–72]. We were

able to obtain a very good picture of molecular modeling using semiempirical calculations [73]. The lowest values of HOF for conjugates of bile acids and sterols (17–22) are observed for cholic acids and its conjugates (19) and (22). The number of hydroxyl groups in the steroid skeleton lowers the value of the determinant of HOF. We observe exactly the same relationship for blocked hydroxyl groups by bolting them with acetate groups. The OAc groups facilitate the formation of intramolecular H-bonds and stable host–guest complexes. These complexes may be stabilized by H-bonding or electrostatic interactions that arise from the OAc groups in the bile acid molecule. The HOF value decreases with the increasing number of OAc groups in the steroid skeleton. Furthermore, for *anti* conformers of deoxycholic and cholic acid derivatives, HOF is lower than for *syn* conformers. On the other hand, the *syn* conformer of the lithocholic acid derivatives (17) and (20) has a higher HOF value than the *anti* conformer and is therefore more durable as no

Fig. 4. Molecular models of conformers *syn* (a) and *anti* (b) of conjugate (19) calculated by PM5 method.

Table 4

Heat of formation (HOF) [kcal/mol] of bile acids (1–3), sterols (13,14) and conjugates (17–22).

$$\Delta\text{HOF}_1 = \text{HOF}_{\text{conjugates syn (17–22)}} - \text{HOF}_{\text{bile acids (1–3)}}$$

$$\Delta\text{HOF}_2 = \text{HOF}_{\text{conjugates anti (17–22)}} - \text{HOF}_{\text{bile acids (1–3)}}$$

$$\Delta\text{HOF}_3 = \text{HOF}_{\text{conjugates syn (17–22)}} - \text{HOF}_{\text{sterols (13–14)}}$$

$$\Delta\text{HOF}_4 = \text{HOF}_{\text{conjugates anti (17–22)}} - \text{HOF}_{\text{sterols (13–14)}}$$

intramolecular interactions are formed. This is due to the absence of electron donating or acceptor groups in its molecule (without OAc groups). The preferential formation of *syn* conformers for conjugates (17) and (20) can therefore be explained by the formation of a molecule that is smaller in volume. However, for the remaining conjugates, deoxycholic and cholic acid derivatives (18–19) and (21–22), *anti* conformers with a lower HOF value are arranged in layers (Fig. 3).

The relations between the experimental ^{13}C and ^1H chemical shifts (δ_{exp}) and the GIAO (Gauge-Independent Atomic Orbitals) magnetic isotopic shielding constants (σ_{calc}), which are widely used in an efficient implementation [65,66], are usually linear and described by the following equation: $\delta_{\text{exp}} = a + b \cdot \sigma_{\text{calc}}$. The slope and intercept of the least-squares correlation line is used to scale the GIAO magnetic isotopic shielding constants, σ_{calc} , and to predict the chemical shifts, $\delta_{\text{pred}} = a + b \cdot \sigma_{\text{calc}}$ (Fig. 5). The parameters a and b are given in Table 5. Usually, the correlations between the experimental chemical shifts and calculated magnetic isotopic shielding constants are better for carbon-13 atoms than for protons. The differences between the calculated and experimental shifts for protons are probably due to the fact that the shifts are calculated for single molecules in gas phase. As can be seen from Fig. 5 the correlation is good for both carbon atoms and for the protons.

3.4. Prediction of activity spectra for substances

Potential pharmacological activities of the synthesized compounds have been determined on the basis of computer-aided drug discovery approach with *in silico* Prediction of Activity Spectra for Substances (PASSs) program. It is based on a robust analysis of the structure-activity relationship in a heterogeneous training set currently including about 250,000 biologically active compounds from different chemical series with about 4,500 types of biological activities. Since only the structural formula of the chemical compound is necessary to obtain a PASS prediction, this approach can be used at the earliest stages of investigation. There are many examples of the successful use of the PASS approach leading to new pharmacological agents [74–78]. The PASS software is useful for the study of biological activity of secondary metabolites. We have selected the types of activities that were predicted for a potential compound with the highest probability (focal activities). If predicted activity is higher than 0.7 ($\text{PA} > 0.7$), the substance is very likely to exhibit the activity in experiment and the chance of the substance being the analogue of a known pharmaceutical agent is also high. If predicted activity is between 0.5 and 0.7 ($0.5 < \text{PA} < 0.7$), the substance is unlikely to exhibit the activity. In experiment and the similarity to known pharmaceutical substance is very limited. Additionally, analyses of the biolog-

Fig. 5. Experimental chemical shifts (δ_{exp} , CDCl_3) in **(19)** vs isotropic magnetic shielding constants (σ_{calc}) from the GIAO/B3LYP/6–311G(d,p) calculations; **(a)** protons and **(b)** carbons-13.

Table 5

Chemical shifts (δ , ppm) in CDCl_3 and calculating GIAO nuclear magnetic shielding tensors (σ_{calc}) for **(19)**. The predicted GIAO chemical shifts were computed from the linear equation $\delta_{\text{exp.}} = a + b \cdot \sigma_{\text{calc}}$ with a and b determined from the fit of the experimental data (r^2 is the correlation coefficient).

ical prediction activity spectra for the new bromoacetoxy derivatives of deoxy and cholic acids (**8–9**), azidoacetoxy derivatives of deoxy and cholic acids (**11–12**), and 5 α -cholestan-3-yl-propynoate (**16**) as well as all conjugates (**17–22**) prepared herein are good examples of *in silico* studies of chemical compounds. We also selected the types of activity that were predicted for a potential compound with the highest probability (focal activities) (Table 6). According to these data the most frequently predicted types of biological activity for (**8–9**) and (**11–12**) are: acylcarnitine hydrolase inhibitor, alkenylglycerophosphocholine hydrolase inhibitor, alkylacetyl glycerophosphatase inhibitor, dextranase inhibitor, glyceryl-ether monooxygenase inhibitor, peptidoglycan glycosyltransferase

inhibitor. Additionally 5 α -cholestan-3-yl-propynoate greater than 0.80 are: anesthetic general, respiratory analeptic, protein-disulfide reductase (glutathione) inhibitor, cholestanetriol 26-monooxygenase inhibitor, prostaglandin-E2 9-reductase inhibitor, CYP2C, CYP3A, CYP2B6 and CYP3A4 substrates, flavin-containing monooxygenase inhibitor, alkenylglycerophosphoethanolamine hydrolase inhibitor, linoleate diol synthase inhibitor, glucan Endo-1,3-beta-D-glucosidase inhibitor, antieczematic, analeptic. Conjugates have significantly lower predicted biological activity than the substrates discussed above. The most important include: pancreatic disorders treatment, glyceryl-ether monooxygenase inhibitor, cholesterol antagonist, antihypercholesterolemic, aypolipemic.

Table 6

"Probability to be Active" (PA) values for the predicted biological activity of (8–9) and (11–12), (16) as well as (15–20).

Table 7

Calculated docking scores for compounds (19) and (22).

Compound	ΔG docking score [kcal/mol]			
	2Q85	1KZN	5V5Z	1EZF
19	–6.877	–9.946	–15.856	–13.361
22	–0.238	–10.34	–15.388	–15.119

3.5. Molecular docking studies

Potential antibacterial and antifungal activity of two representative compounds was determined in docking study. In this case two of the most common molecular targets which are responsible for antibacterial activity were chosen: *E. coli* MurB (PDB ID: 2Q85) [79] and Gyrase (PDB ID: 1KZN) [80]. In terms of antifungal activity two of the most significant molecular targets are: CYP51_{Ca} (PDB ID: 5V5Z) [81] and Squalene synthase (PDB ID: 1EZF) [82] and that targets were chosen for docking study. Based on calculated docking score (Table 7), most of considered compounds may exhibit potential antibacterial and antifungal activity, however antifungal activity seems to be stronger. All docked compounds occupy the same binding pocket as the parent co-crystallized ligands.

3.5.1. Docking to antibacterial drug targets

During docking to *E. coli* MurB protein (Fig. 6), forming of strong hydrogen bond with Arg327 was observed for both compounds. Ligands adopt bent conformation in the binding site. Ligand 19 exhibited forming of additional strong hydrogen bonds (bond length ≤ 2.1 Å) with Gln120 and Arg159. For the same ligand, we identified stabilizing hydrophobic contact (with Ile110,

Leu290, Val291 and Pro111) as well. The binding mode for compound 19 is similar to those reported by A. Geronikaki [83]. Ligand 22 (Fig. 7) with the highest docking score (ΔG = –0.238 kcal/mol) exhibited many steric clashes which may suggest it does not fit to the binding pocket which may implies low activity. In terms of binding to gyrase (Table 7, 1KZN) both compounds exhibit low docking score and forming hydrogen bonds with Arg136 and Arg76 (bond length ≤ 2.2 Å) and cation-π interaction between 1,2,3-triazole ring and Arg76. Some stabilizing hydrophobic interactions were identified as well as less number of steric clashes than for 2Q85.

3.5.2. Docking to antifungal drug targets

For both targets, docking study revealed the lowest docking scores and bent conformations for considered compounds. Ligand 19 (Fig. 8) forms strong hydrogen bond (bond length = 2.6 Å) between His377 and lanosterol 14 alpha-demethylase of *C. albicans* (Table 7, CYP51_{Ca}) whereas compound 22 (Fig. 8) forms hydrogen interaction with Met508 (bond length = 2.3 Å). In terms of stabilizing hydrophobic interactions (eg. Phe233 or Ile231) one of the most crucial is interaction between compound 19 and Hem601. This interaction was not observed for ligand 22. For both ligands just a few steric clashes were identified which shows that ligands fit into binding pocket well. Docked ligand 19 to Squalene synthase (Fig. 9, Table 7) revealed forming of two strong hydrogen bonds with Arg218 and Arg52 (bond length ≤ 2.1 Å) while ligand 22 showed only one hydrogen bond with Gln212 (bond length ≤ 2.1 Å). Some weak stabilizing hydrophobic interactions were identified as well as a few steric clashes. Both compounds adopt bent conformation.

Fig. 6. Ligand interactions and binding mode for compound **19** and **22** in 2Q85. A, C – represents ligand **19** (green); B, D – represents ligand **22** (yellow).

Fig. 7. Ligand interactions and binding mode for compound **19** and **22** in 1KZN. A, C – represents ligand **19** (green); B, D – represents ligand **22** (yellow).

Fig. 8. Ligand interactions and binding mode for compound **19** and **22** in 5V5Z. A, C – represents ligand **19** (green); B, D – represents ligand **22** (yellow).

Fig. 9. Ligand interactions and binding mode for compound **19** and **22** in 1EZf. A, C – represents ligand **19** (green); B, D – represents ligand **22** (yellow).

4. Conclusions

The increasing interest in the synthesis of new bile acid conjugates using the click chemistry method significantly influences on the development of supramolecular chemistry, pharmacology and medicine. Design, preparation, enormous biological potential and a wide range of physicochemical properties of compounds containing the 1,2,3-triazole ring allow them to be used as artificial receptors, organogels or new complexing and transporting drugs. In conclusion, six new conjugates of bile acids and sterols linked with 1,2,3-triazole ring (**17–22**) in a way: head (sterol)–tail (bile acid) were prepared from cholesterol/cholestanol esters of propiolic acid and azidoacetyl substituted derivatives of bile acids in *t*-BuOH/MeOH mixture in the presence of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ and sodium ascorbate at 60 °C. Moreover, two bromoacetyl (**8**) and (**9**) as well as two azidoacetyl (**11**) and (**12**) substituted derivatives of bile acids were prepared from dehydrocholic or cholic acid in dry dichloromethane with bromoacetic acid bromide and in THF with sodium azide at 50 °C, appropriately. Additionally cholestanyl ester of propiolic acid (**16**) were prepared from cholestanol in dichloromethane. These new compounds linked with 1,2,3-triazole ring were characterized by analytical methods such as spectroscopic (NMR, FT-IR), spectrometry (ESI-MS), semiempirical calculation (PM5) and PASS. The effects of inter and intramolecular interactions and conformation of molecules have been precisely explained by comparison of experimental data taken in the condensed phase and calculation data (gas phase). The magnetic isotopic shielding constants, σ_{calc} , were calculated by the GIAO/B3LYP/6–311G(dp) level of theory. Linear correlations between the experimental ^1H and ^{13}C chemical shifts and the computed screening constants confirm the optimized geometry. The potential antibacterial and antifungal activity of two representative compounds were determined in the docking study. Based on the calculated docking score most of the considered compounds may exhibit potential antibacterial and antifungal activity, however, antifungal activity seems to be stronger.

5. Author contributions

The listed authors contributed to this work as described in the following. Anna Kawka performed the synthesis of cholesterol and bile acid derivatives. Grzegorz Hajdaś performed the synthesis of cholestanol and bile acid derivatives. Hanna Koenig was purifying compounds and interpreted the results. Iwona Kowalczyk

performed quantum chemical calculations. Tomasz Pospieszny carried out of the synthetic work, interpretation of results, performed semiempirical calculations (PM5) and Prediction of Activity Spectra for Substances (PASS). Damian Kułaga performed and described molecular docking studies. All authors contributed with valuable discussions and scientific input and approved the final version.

Declaration of Competing Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

OŚWIADCZENIE

Oświadczamy, że w monografii „Triazole-Based Modification of Bile Acids: Promising Strategies for Combating Infections and Cancer – A Review” opublikowanej w książce *Na pograniczu chemii, biologii i fizyki – rozwój nauk. Tom 6* wkład wymienionych Autorów w przygotowanie publikacji jest następujący:

LP	Imię i nazwisko Autora	Wkład merytoryczny Autora	Podpis Autora
1	Dr inż. Hanna Koenig	Dyskusja wyników, współudział w opracowaniu oryginalnego manuskryptu	
2	Prof. UAM dr hab. Tomasz Pospieszny	Dyskusja wyników, współudział w opracowaniu oryginalnego manuskryptu	

Poznań, 5 maja 2025 r.

OŚWIADCZENIE

Oświadczamy, że w artykule „Steroid and Bioactive Molecule Conjugates: Improving Therapeutic Approaches in Disease Management” opublikowanym w czasopiśmie *Bioorganic Chemistry*, 2024, 153, 107933 wkład wymienionych Autorów w przygotowanie publikacji jest następujący:

LP	Imię i nazwisko Autora	Wkład merytoryczny Autora	Podpis Autora
1	Dr inż. Hanna Koenig	Dyskusja wyników, współudział w opracowaniu oryginalnego manuskryptu	
2	Prof. UAM dr hab. Tomasz Pospieszny	Dyskusja wyników, współudział w opracowaniu oryginalnego manuskryptu	

Poznań, 5 maja 2025 r.

OŚWIADCZENIE

Oświadczamy, że w artykule „Exploring Triazole-Connected Steroid-Pyrimidine Hybrids: Synthesis, Spectroscopic Characterization, and Biological Assessment” opublikowanym w czasopiśmie *ACS Omega*, **2024**, *9*, 37995–38014 wkład wymienionych Autorów w przygotowanie publikacji jest następujący:

LP	Imię i nazwisko Autora	Wkład merytoryczny Autora	Podpis Autora
1	Mgr Damian Nowak	Wykonanie oraz interpretacja wyników dokowania molekularnego, współudział w opracowaniu oryginalnego manuskryptu	 PODPIS ZAUFANY DAMIAN NOWAK 13.05.2025 11:25:11 [GMT+2] Dokument podpisany elektronicznie podpisem zaufanym
2	Dr inż. Hanna Koenig	Dyskusja wyników, współudział w opracowaniu oryginalnego manuskryptu	
3	Prof. UAM dr hab. Tomasz Pospieszny	Dyskusja wyników, współudział w opracowaniu oryginalnego manuskryptu	

Poznań, 5 maja 2025 r.

OŚWIADCZENIE

Oświadczamy, że w rozdziale „From Squalamine to Triazole Ring Derivatives Exploring the Versatility of Steroidal Bioconjugates” opublikowanym w książce *Studies in Natural Products Chemistry* Edited by Atta-ur Rahman, Elsevier, Amsterdam, Netherlands 2024, 82, 247–283 wkład wymienionych Autorów w przygotowanie publikacji jest następujący:

LP	Imię i nazwisko Autora	Wkład merytoryczny Autora	Podpis Autora
1	Dr inż. Hanna Koenig	Dyskusja wyników, współudział w opracowaniu oryginalnego manuskryptu	
2	Prof. UAM dr hab. Tomasz Pospieszny	Dyskusja wyników, współudział w opracowaniu oryginalnego manuskryptu, autor korespondencyjny	

Poznań, 5 maja 2025 r.

OŚWIADCZENIE

Oświadczamy, że w artykule „Quasi-Podands with 1,2,3-Triazole Rings from Bile Acid Derivatives: Synthesis, and Spectroscopic and Theoretical Studies” opublikowanym w czasopiśmie *Journal of Organic Chemistry*, 2024, 89 (11), 7561–7572 wkład wymienionych Autorów w przygotowanie publikacji jest następujący:

LP	Imię i nazwisko Autora	Wkład merytoryczny Autora	Podpis Autora
1	Dr inż. Hanna Koenig	Dyskusja wyników, współudział w opracowaniu oryginalnego manuskryptu	
2	Mgr Damian Nowak	Wykonanie i opisanie wyników dokowania molekularnego, współudział w opracowaniu oryginalnego manuskryptu	 PODPIS ZAUFANY DAMIAN NOWAK 13.05.2025 11:23:23 [GMT+2] Dokument podpisany elektronicznie podpisem zaufanym
3	Prof. UAM dr hab. Tomasz Pospieszny	Dyskusja wyników, współudział w opracowaniu oryginalnego manuskryptu, autor korespondencyjny
